(54) Title: COMPOSITION AND METHOD FOR REGULATION OF BODY WEIGHT AND ASSOCIATED CONDITIONS

(57) Abstract

Described are methods and compositions for regulating body weight and/or regulating the rate of weight gain or loss, and particularly, for treating or preventing obesity. Specifically, methods of administering varying levels of circulating proopiomelanocortin peptides or analogs thereof to an animal, alone or in combination with leptin or other body weight regulating agents are disclosed. Methods and compositions for treating a variety of disorders associated with or caused by undesirable body weight are also described. Also described are methods for identifying compounds useful for regulation of body weight and associated conditions. In particular, methods are disclosed for identification of compounds that preferentially bind to and/or activate peripheral melanocortin receptors and which minimize binding and/or activation of central melanocortin receptors. Also described is a genetically modified non-human animal model for studying the peripheral and central pathways of energy homeostasis. Also disclosed are methods of identifying compounds for regulating such pathways and a POMC mutant mouse.

FIELD OF THE INVENTION

10

15

20

25

and wasting disease are frequently used interchangeably to refer to wasting conditions, there is at least one body of research which differentiates cachexia from wasting syndrome as a loss of fat-free mass, and particularly, body cell mass (Mayer, 1999, *J. Nutr.* 129(1S Suppl.): 256S-259S). Sarcopenia, yet another such disorder which can affect the aging individual, is typically characterized by loss of muscle mass. End stage wasting disease as described above can develop in individuals suffering from either cachexia or sarcopenia.

In addition to the obvious health risks associated with being overweight or underweight, the tangential detrimental effects of such conditions are equally troublesome. For the obese individual, health effects can include a myriad of physical conditions related to, or affected by, excess body weight (e.g., cardiovascular disease, diabetes, cancer, hypertension, etc.) as well as physiological damage due to an overweight person's loss of self-esteem, depression, etc. For example, obesity, and particularly upper body obesity, is frequently associated with NIDDM. Non-insulin dependent diabetes mellitus (NIDDM or Type II diabetes) is a metabolic disorder that is characterized by the failure of body tissues to store carbohydrates at a normal rate. Resistance to the action of insulin is the most common characteristic of a Type II diabetic. When this resistance exceeds the capacity of the insulin-producing beta cells of the Islets of Langerhans to produce insulin, clinical diabetes results. In addition to NIDDM, being overweight, even in the absence of clinical obesity, can significantly increase the risk of developing certain other conditions, and/or of exacerbating the symptoms associated with the condition once developed. For example, the risk of inquiring several forms of cancer is increased in obese patients. Such cancers include breast cancer and colon cancer. Moreover, it has been known for years that excess body weight can be a risk factor for cardiovascular disease, hypertension, stroke and gall bladder disease. Obesity can also contribute to the risk of acquiring, or exacerbating, respiratory problems and osteoarthritis.

Other conditions that are frequently associated with excess gain of body weight are affective and mood disorders, including atypical depression or dysthymia. Some patients may alternatively experience undesired loss of body weight. It has previously been shown that in patients with an affective disorder characterized by higher than normal levels of HPA axis activity, leptin levels are also increased from normal levels in the blood of such patients (U.S. Patent No. 5,866,547 to Flier et al., incorporated herein by

reference in its entirety). High cerebrospinal fluid (brain) leptin levels are needed to suppress the increased activity of the HPA axis in these patients.

Another factor which can significantly contribute to an individual's propensity to gain weight and/or an inability to lose weight may be a side effect associated with one or more pharmaceutical compounds that the individual is taking to treat another condition. For example, epilepsy, attention deficit hyperactivity disorder (ADHD), and recently, migraine, are often treated with the drug, valproic acid, also known commercially as Depakote, which has the well known and undesirable side effect of increasing body weight. Other drugs having a similar side effect include lithium, commonly used for bipolar disorder (manic depression) and a several other antidepressants, including tricyclic antidepressants and several selective serotonin reuptake inhibitors (SSRIs) including fluoxetine, also known commercially as Prozac. There are a number of other drugs which have similar side effects, or the opposite side effect (i.e., undesired loss of body weight), including many drugs used for chemotherapy. Indeed, Such side effects can have serious implications for the patient's compliance with the drug therapy, as well as the patient's general well being and health. Indeed, many patients are likely to choose a lower body weight and greater self esteem over the treatment of what can be a disabling and destructive disorder, which reduces the ability of both patient and physician to maintain control over the disorder. When the disorder is a bipolar disorder, for example, non-compliance can be life-threatening.

For the underweight individual, conditions related to or affected by low body weight can include heart failure, susceptibility to infectious disease as a result of immune system weakness, and depression. Moreover, the rise in bulimia and anorexia in the past few decades is alarming, and illustrates the disturbing emphasis on ideal body size and shape regardless of the severe health consequences.

In 1963, Kennedy and Mitra proposed that puberty is linked to body weight and more specifically, to fat storage which is concluded to be one of the signals responsible for the initiation of hypothalamic control of ovarian function (*J. Physiol.* 166:408). Other researchers have proposed that the loss or restoration of menstrual cycles in young girls is related to a minimum weight for height (Frisch and McArthur, 1974, *Science* 185:949). Frisch and McArthur proposed that normal girls become relatively fatter from menarche

to reproductive maturity. Taken together, these studies indicate that there is a relationship between the initiation of reproduction and adiposity. In support of this relationship were the observations that very lean young female ballet dancers and college rowers have a delayed puberty (Frisch et al., 1980, *NEJM* 303:17 and Frisch et al., 1981, *JAMA* 246:1559), whereas obese girls have an acceleration of puberty (Zacharias et al., 1970, *Am. J. Obs. Gyn.* 108:833). The amenorrhea of extremely lean women was attributed to loss of fat and hypothalamic dysfunction (Vigersky et al., 1977, *NEJM* 297:1141). Based on such studies, Frisch et al. formed a hypothesis that a metabolic signal may be responsible for the initiation of reproduction, or the "critical weight" hypothesis (Frisch et al., 1970, *Science* 109:397). Frisch additionally proposed that adipose tissue is a direct regulator of female reproduction since it converts androgens to estrogens via aromatization (R.E. Frisch, 1990, *Adipose Tissue and Reproduction Progress in Reproductive Biology and Medicine*, vol. 14 and Sifteri, 1981, *J. Endocrinol.* 89:119).

Radical treatments to treat obesity include surgical procedures such as liposuction and stomach stapling. In addition, numerous drugs have been utilized in an effort to regulate a person's metabolism and/or to decrease appetite. Many of such drugs, however, have demonstrated harmful effects and have since been taken off of the market. Other replacement drug therapies have proven less effective, and the long term health consequences of such drugs are unknown. For the underweight individual, who may be suffering from undesired weight loss due to a disease such as cancer or AIDS, efforts to maintain or gain weight can be equally problematic.

Faced with such a long felt, but unsolved need for simple and effective methods for regulating body weight and for treating conditions associated with dysregulation of body weight, researchers, over the last several decades, have expended literally hundreds of millions of dollars to investigate compounds that can be used to treat body weight problems such as obesity without the negative implications experienced with other, previously tested, weight regulating drugs. While altering appetite can affect weight, so can the regulation of the fat stores in adipose tissue. This latter approach has been an under-appreciated field relative to regulation of appetite. For instance, compared to the list of compounds directed at inhibition of energy uptake (appetite suppressants), very few

compounds have been identified which stimulate fat mobilization or suppress lipid sequestration.

Physiologists have postulated for years that, when a mammal overeats, the resulting excess fat stores signal to the brain that the body is obese which, in turn, causes the body to eat less and burn more dietary fat. G.R. Hervey, *Nature* (London), 227:629-631 (1969). This model of feedback inhibition is supported by parabiotic experiments, which implicates circulating hormones controlling adiposity. Genetic studies in model organisms, especially the mouse, have allowed the identification of molecules important for the regulation of body weight. These include leptin (Zhang et al., 1995, *Nature* 372:425-432, incorporated herein by reference in its entirety), a leptin receptor (Tartaglia et al., 1995, *Cell* 83:1263-1271) and a melanocortin receptor (Huszar et al., 1997, *Cell* 88:131-141).

Findings from several lines of investigations have placed proopiomelanocortin (POMC) and the peptides derived from it at a pivotal position in the central pathways for energy homeostasis. Obesity in the autosomal dominant *lethal yellow* (A^y/a) mouse, for example, is caused by ectopic expression of the agouti protein in the brain, where it antagonizes the melanocortin receptor 4 (MC4-R), a receptor found within the central nervous system (Lu et al., 1994, *Nature* 371:799-802). Agouti-related protein (AgRP) is normally expressed in the brain and antagonizes MC4-R. In transgenic mice, overexpression of AgRP results in obesity (Graham et al, 1997, *Nat. Genet.* 17:273-274 and Ollmann et al., 1997, *Science* 278:135-138). Targeted deletion of the MC4-R produces obesity similar to that of A^y mice, which is characterized by both adult onset obesity and increased linear growth (Huszar et al., 1997, *Cell* 88:131-141). Pharmacological evidence has further suggested the importance of a melanocortinerpic pathway in the *central* regulation (i.e., via the central nervous system) of energy balance: decreased feeding was observed after central administration of an MC4-R agonist (α -MSH analog) to normal mice and increased feeding after central administration of a synthetic MC4-R antagonist to normal mice when measured for 12 hours (Fan et al., 1997, *Nature* 385:165-168). Further demonstrating the focus of previous investigators on the *central* pathways of energy homeostasis, PCT Publication WO 97/47316 and corresponding U.S. Patent Nos. 5,908,609 and 5,932,779 to Lee et al., which are

incorporated herein by reference in their entireties, disclose drug screening assays and diagnostic and therapeutic methods for treating body weight disorders by targeting the MC4-R. Lee et al. describe identifying compounds that target MC4-R and describe administering such compounds so that delivery to the brain is optimized.

5 Understanding of the regulation of fat stores was greatly advanced by the discovery of leptin, the gene affected in the obese (*ob*) mutation. Leptin is secreted by adipose tissue, and its levels increase with increasing fat stores. Leptin is known to have both central and peripheral effects. There are high affinity receptors for leptin in the hypothalamus. Absence of either leptin or the leptin receptor leads to morbid obesity,
10 presumably because the hypothalamus receives no fat signal, and accordingly acts as if the animal is completely without fat stores, and in some manner directs adipocytes to accumulate fat. The use of leptin to treat obesity in mice, however, requires very high, non-physiological doses. Thus, leptin alone has not been found to be a particularly useful anti-obesity agent.

15 To treat wasting and cachexia in patients such as the elderly, AIDS patients and cancer patients, anabolic steroids, growth hormone, dietary regimens, erythropoietin, cytokine therapy and anti-cytokine therapy, among other therapies, have been used to try to improve the condition of such patients. Such therapies cross a wide range of target cells, may have undesirable systemic side effects, may require toxic doses to work, and
20 may not be sufficient to completely address the complex biological dysfunction related to different types of wasting disorders, however, and therefore, research is ongoing in the effort to find additional solutions to this problem.

 Therefore, there remains a need in the art for a simple, safe and effective method for controlling body weight and for treating conditions related to or caused by undesired
25 and/or health-compromising body weight, and for methods to identify compounds useful in such methods.

SUMMARY OF THE INVENTION

30 While a majority of the prior art methods to regulate body weight have involved the regulation of appetite (i.e., by regulation of central pathways of energy homeostasis), the present invention is primarily directed to the regulation of the fat stores in adipose

tissue (i.e., peripheral pathways of energy homeostasis). The present invention is specifically directed to a method and compound for controlling body weight (i.e., decreasing body weight, reducing weight gain, increasing body weight, or reducing weight loss) and conditions associated with or caused by undesirable body weight. Such a method comprises administering to an animal that is at risk for or has undesired body weight and/or a detrimental condition related thereto a therapeutic composition that regulates *the peripheral* melanocortinerger pathway and/or the leptinerger pathway of energy homeostasis.

One embodiment of the present invention relates to a method to regulate body weight in an animal, comprising administering to the animal a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective to measurably regulate body weight in the animal, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. The POMC compound can include, but is not limited to, a melanocortin compound and a lipocortin compound. In a preferred embodiment, the compound is a melanocortin compound. Melanocortin compounds can include, for example, melanocyte stimulating hormone (MSH), a fragment of MSH, a homologue of MSH, a peptide mimetic of MSH, a non-peptide mimetic of MSH, and a fusion protein comprising an MSH protein or fragment thereof. In one embodiment, the compound is selected from the group of α -MSH, β -MSH and γ -MSH. In another embodiment, the compound is a peptide mimetic of MSH. In a preferred embodiment, the compound is an analog of a peptide having an amino acid sequence represented herein by SEQ ID NO:2.

In one embodiment, the POMC compound is an α -MSH analog selected from the group of:

- a. [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH, wherein the Cys residues are connected by a disulfide bond;
- b. Ac-[Nle⁴, X_{aa}⁵, His⁶, X_{aa}⁷, Arg⁷, Trp⁹, X_{aa}¹⁰]-NH₂, (SEQ ID NO:3)
wherein X_{aa}⁵ is Glu or Asp, X_{aa}⁷ is Phe or D-Phe and X_{aa}¹⁰ is a dibasic amino acid; Lys; ornithine; 2,4,-diaminobutyric acid; or 2,3 diaminopropionic acid (Dpr);

c. $\text{Ac-[Cys}^4, \text{Cys}^{10}]\alpha\text{-MSH}_{1-13}\text{NH}_2$;

d. $\text{R}_1\text{-W-X-Y-Z-R}_2$,

wherein R_1 is selected from the group consisting of Ac-Gly-, Ac-Met-Glu-, Ac-Nle-Glu- and Ac-Tyr-Glu-;

5 W is selected from the group consisting of -His- and -D-His-;

X is selected from the group consisting of -Phe-, -D-Phe-, -Tyr-, -D-Tyr-, (-pNO₂)D-Phe⁷-;

Y is selected from the group consisting of -Arg- and -D-Arg-;

Z is selected from the group consisting of -Trp- and -D-Trp-; and,

10 R_2 is selected from the group consisting of -NH₂-, -Gly-NH₂-, and -Gly-Lys-NH₂-;

e. $\text{Ac-Ser-Tyr-Ser-M-Glu-His-D-Phe-Arg-Trp-Gly-Lys-Pro-Val-NH}_2$ (SEQ ID NO:4),

wherein M is selected from the group consisting of Met, Nle, and Cys;

15 f. $[\text{Nle}^4, \text{D-Phe}^7]\text{-}\alpha\text{-MSH}$;

g. $[\text{Nle}^4, \text{D-Phe}^7]\text{-}\alpha\text{-MSH}_{4-10}$;

h. $[\text{Nle}^4, \text{D-Phe}^7]\text{-}\alpha\text{-MSH}_{4-11}$;

i. $[\text{Nle}^4, \text{D-Phe}^7, \text{D-Trp}^9]\text{-}\alpha\text{-MSH}_{4-11}$;

j. $[\text{Nle}^4, \text{D-Phe}^7]\text{-}\alpha\text{-MSH}_{4-9}$;

20 k. $\text{Ac-[Nle}^4, \text{AA}^5, \text{D-Phe}^7, \text{AA}^{10}]\text{-R}_1$ or $\text{Ac-[Nle}^4, \text{AA}^5, \text{D-Phe}^7, \text{AA}^{11}]\text{-R}_2$;

wherein AA⁵ may be either a L- or D- amino acid having an omega amino or carboxyl group in the side chain, e.g., α,γ -diaminopropionic acid, α,γ -diaminobutyric acid, Orn, Lys, α,β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

25 wherein AA¹⁰ may be diaminopropionic acid, α,γ -diaminobutyric acid, Orn, Lys, α,β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

wherein R_1 is the designation $\alpha\text{-MSH}_{1-13}\text{NH}_2$, $\alpha\text{-MSH}_{1-12}\text{NH}_2$, $\alpha\text{-MSH}_{1-11}\text{NH}_2$, $\alpha\text{-MSH}_{4-13}\text{NH}_2$, or $\alpha\text{-MSH}_{4-10}\text{NH}_2$;

30 wherein AA¹¹ may be L- or D- amino acid having an omega-amino or carboxyl group in the side chain, e.g., α,β -diaminopropionic acid; α,γ -

diaminobutyric acid, Orn, Lys, α -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

wherein R_2 is the designation α -MSH₁₋₁₃NH₂, α -MSH₁₋₁₂NH₂, α -MSH₁₋₁₁NH₂, α -MSH₄₋₁₃NH₂, or α -MSH₄₋₁₀NH₂; and,

5

wherein Xxx may be from 1 to 5 α -amino acid residues each of which may be of L- or D- configuration, or a linear or branched chain spacer;

l.

m.

10

n.

wherein R^1 is a substituted or unsubstituted aromatic radical;

15

R^2 is hydrogen or a methyl group;

R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

10

R^4 is glutamic acid, alanine, -amino butyric acid, valine, leucine or isoleucine;

R^5 is histidine, glutamic acid, alanine, valine, leucine or isoleucine;

R^6 and R^7 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

5 R^8 and R^9 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂,

10

and,

n is an integer greater than or equal to 2;

o.

15

wherein R^1 is phenyl, indole, p-hydroxyphenyl, p-aminophenyl, imidazole, 1-naphthyl adamantyl or alkylphenyl, 2-naphthyl;

R^2 is hydrogen or a methyl group;

20 R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂,

25

and,

n is an integer greater than or equal to 2; and wherein the cyclized portion of the compound is conformationally restricted in a manner which is compatible with the reactivity of the compound with receptors of the central nervous system. In one aspect, the POMC compound is a peptide comprising an amino acid sequence represented by SEQ ID NO:1.

A POMC compound preferably has the following identifying characteristics: (1) an ability to bind to a POMC receptor that is expressed in peripheral tissues; and, (2) a biological activity selected from the group consisting of stimulation of lipolysis and inhibition of the uptake of fatty acids by adipocytes. The POMC receptor is preferably selected from the group of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R), with MC2-R being more preferred. In one embodiment, the POMC compound binds to a melanocortin receptor selected from the group consisting of MC2-R and melanocortin 5-receptor (MC5-R), with a higher affinity than to melanocortin-4 receptors (MC4-R). In another embodiment, the compound binds to a melanocortin receptor selected from the group consisting of MC2-R and melanocortin 5-receptor (MC5-R), and does not bind to any other melanocortin receptor under physiological conditions. In another embodiment, the compound binds to MC2-R, and does not bind to any other melanocortin receptor under physiological conditions. In yet another embodiment, the compound does not bind to MC4-R under physiological conditions. Preferably, the compound preferentially activates melanocortin-2 receptors (MC2-R) as compared to melanocortin-4 receptors (MC4-R). In one embodiment, compound does not activate MC4-R under physiological conditions. Preferably, administration of the compound is insufficient to cause a statistically significant change in the appetite of the animal as compared to before administration of the compound.

The therapeutic composition can be administered by a route selected from the group consisting of transdermally, topically, parenterally and orally.—Preferably, the therapeutic composition is not administered directly to the central nervous system of the animal. In one embodiment, the therapeutic composition is administered in a controlled release formulation. A POMC compound is preferably administered in a dose of from about 0.1 μ g to about 10 mg per kg body weight of the animal, and in another aspect, in a dose of from about 1 μ g to about 10 mg per kg body weight of the animal. In one

aspect, the POMC compound is administered in a dose of from about 40 µg to about 1 mg per kg body weight of the animal. Preferably, the POMC compound is from about 0.1% to about 90% of the therapeutic composition by weight, and in one embodiment, the POMC compound is from about 0.1% to about 1% of the therapeutic composition by weight. In one embodiment, the composition further comprises an antagonist of MC4-R. In another aspect, the composition further comprises an agent that inhibits binding of the POMC compound to an MC4-R. In another aspect, the composition further comprises an agent which inhibits the POMC compound from entering the central nervous system of the animal.

10 In one embodiment, the method is effective to measurably decrease body weight in the animal. A decrease in body weight in the animal can be measured within at least about two weeks of the step of administering the compound, and more preferably at least about one week, and more preferably at least about 3 days, and even more preferably at least about 24 hours of the step of administering the compound.

15 A preferred animal to which to administer the POMC compound includes an animal that has serum leptin levels between about 0 ng/ml and 50 ng/ml prior to the step of administration, and/or an animal that has serum MSH levels between about 0 ng/ml and 10 ng/ml prior to the step of administration. In one aspect, the animal has a ratio of serum MSH levels to serum leptin levels of greater than about 1:100 prior to the step of administration. In another aspect, the animal is a human having a body mass index (BMI) of greater than 27 kilograms per square meter.

20 In one embodiment, the composition further comprises another body weight regulating agent. Preferably, the body weight regulating agent is leptin. In this embodiment, the composition comprises a ratio of the POMC compound to leptin of about 1:100. In another aspect, the composition comprises the leptin in a dose of from about 0.1 µg to about 100 mg per kg body weight of the animal.

25 In another embodiment of the method of the present invention, the therapeutic composition is administered in an amount effective to measurably increase body weight in the animal or to decrease body weight loss in the animal. In one embodiment of this aspect of the present method, the POMC compound is combined with another body weight regulating agent. Such a body weight regulating agent can include, but is not

30

limited to, an anabolic steroid, a growth hormone, erythropoietin, a cytokine, and an anti-cytokine agent. In this embodiment, the POMC compound is a proopiomelanocortin (POMC) antagonist compound. Preferably, the compound has the following identifying characteristics: (1) an ability to bind to a POMC receptor that is expressed in peripheral tissues; and, (2) a biological activity selected from the group consisting of inhibition of lipolysis and stimulation of the uptake of fatty acids by adipocytes. Preferably, the receptor is selected from the group of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R), with MC2-R being more preferred. Preferably, the antagonist compound is selected from the group consisting of a melanocortin antagonist compound and a lipocortin antagonist compound, with melanocortin antagonist compounds being more preferred. In one aspect, the antagonist compound is selected from the group of a fragment of MSH having MSH antagonist action, a homologue of MSH having MSH antagonist action, a peptide mimetic of MSH having MSH antagonist action, a non-peptide mimetic of MSH having MSH antagonist action, and a fusion protein comprising any of the MSH antagonist compounds. Preferably, the antagonist compound is selected from the group of α -MSH antagonist, β -MSH antagonist and γ -MSH antagonist. In one aspect, the antagonist compound is a peptide mimetic of MSH. In another aspect, the antagonist compound is an MSH analog selected from the group consisting of:

a.

20

b.

C.

wherein R^1 is a substituted or unsubstituted aromatic radical;

5 R^2 is hydrogen or a methyl group;

R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

R^4 is glutamic acid, alanine, -amino butyric acid, valine, leucine or isoleucine;

R^5 is histidine, glutamic acid, alanine, valine, leucine or isoleucine;

10 R^6 and R^7 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

R^8 and R^9 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

X and Y are sulfur, methylene, SO or SO_2 ;

15 Z is $-\text{NH}_2$,

and,

n is an integer greater than or equal to 2; and,

20

d.

wherein R¹ is phenyl, indole, p-hydroxyphenyl, p-aminophenyl, imidazole, 1-naphthyl, adamantyl or alkylphenyl, 2-naphthyl;

R² is hydrogen or a methyl group;

R³ is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂;

and,

n is an integer greater than or equal to 2; and wherein the cyclized portion of the compound is conformationally restricted in a manner which is compatible with the reactivity of the compound with receptors of the central nervous system.

Preferably, in the method of the present invention, the animal is a human.

Another embodiment of the present invention relates to a method for inhibition of free fatty acid uptake and/or stimulation of lipolysis in an animal, comprising administering to the periphery of an animal a POMC compound in an amount effective to produce a result selected from the group consisting of stimulation of lipolysis and inhibition of fatty acid uptake. In this embodiment, the amount is preferably insufficient to cause a statistically significant change in the appetite of the animal after administration of the compound as compared to before administration of the compound. Various aspects of such a method are as described for the methods above.

Yet another embodiment of the present invention relates to a method of regulating the body weight of an animal, comprising administering to an animal a POMC compound in an amount effective to bind to POMC receptors expressed by the animal in the animal's

peripheral tissues, the effective amount: (a) being insufficient to substantially change the appetite of the animal after the step of administering as compared to before the step of administering; (b) being between about 0.1 μ g and about 10 mg per kg of body weight of the animal; (c) being sufficient to affect a biological activity selected from the group consisting of: (i) lipolysis; and, (ii) uptake of fatty acids by adipocytes in the animal; and, (d) being effective to measurably increase or decrease the body weight of the animal after the compound has been administered to the animal. Various aspects of such a method are as described for the methods above.

Another embodiment of the present invention relates to a method to regulate body weight in an animal, comprising modulating the activity of a melanocortin receptor selected from the group consisting of melanocortin 2-receptor and melanocortin 5-receptor. In this embodiment, the melanocortin receptor is preferably a melanocortin 2-receptor. The step of modulating can include administering to the periphery of the animal a compound which regulates the melanocortin receptor. The compound can include, but is not limited to a POMC compound, an antibody that selectively binds to the melanocortin receptor, and a soluble melanocortin receptor. The step of modulating can include, in one embodiment, administering an effective amount of a compound that increases expression of the melanocortin 2-receptor and induces weight loss. The step of modulating preferably comprises administering an effective amount of a compound that decreases expression of the melanocortin 2-receptor and induces weight gain. Various aspects of such a method are as described for the methods above.

Yet another embodiment of the present invention relates to a method for regulating metabolic efficiency in an animal, comprising: (a) measuring serum MSH levels in an animal; (b) identifying animals having serum MSH levels of less than about 0.1 ng/ml; and, (c) administering to the periphery of the animals identified in (b) a composition comprising a compound selected from the group consisting of a POMC compound and leptin, wherein the compound is administered in an amount effective to increase serum MSH levels in the animal to level effective to produce a result selected from the group consisting of stimulating lipolysis and inhibiting fatty acid uptake in the animal. Preferably, the compound is administered in an amount effective to produce a measurable

decrease in body weight of the animal. Various aspects of such a method are as described for the methods above.

Another embodiment of the present invention relates to a therapeutic composition that regulates the peripheral melanocortinerbic and/or leptinerbic pathways of energy homeostasis in an animal, comprising: (a) a first body weight regulating agent that is a proopiomelanocortin (POMC) compound; and, (b) a second body weight regulating agent that is not a proopiomelanocortin (POMC) compound. The POMC compound is preferably a POMC compound as described above, preferably provided in the doses and formulated as described above. In one embodiment, the second body weight regulating agent is leptin. Preferably, the composition comprises a ratio of the POMC compound to leptin of 1:100, and in another aspect, a ratio of the POMC compound to leptin of 1:25, and in another aspect, a ratio of the POMC compound to leptin of 1:10. The dose of leptin is preferably from about 0.1 μ g to about 100 mg per kg body weight of the animal, and more preferably, from about 0.1 μ g to about 10 mg per kg body weight of the animal, and in another aspect, is from about 1 μ g to about 10 mg per kg body weight of the animal. In another embodiment, the second body weight regulating agent is selected from the group consisting of an anabolic steroid, a growth hormone, erythropoietin, a cytokine, and an anti-cytokine agent. The therapeutic composition preferably further comprises a pharmaceutically acceptable excipient. Such a pharmaceutically acceptable excipient can, in one embodiment, prolong the presence of the therapeutic composition in the bloodstream of a animal.

Yet another embodiment of the present invention relates to a method for treating an affective and mood disorder in an animal, comprising administering to an animal at risk for or suffering from an affective mood disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective to measurably ameliorate the disorder in the animal, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. The affective and mood disorder can include, but is not limited to, depression and dysthymia. In one aspect, the depression is atypical depression.

Another embodiment of the present invention relates to a method to treat an obesity-associated disorder in an animal, comprising administering to an animal suffering from or at risk for an obesity-associated disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective to measurably decrease body weight or weight gain in the animal, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. The obesity-associated disorder can include, but is not limited to, non-insulin dependent diabetes mellitus, cardiovascular disease, cancer, hypertension, osteoarthritis, stroke, respiratory problems, and gall bladder disease.

Another embodiment of the present invention relates to a method for treating a reproductive disorder in an animal, comprising administering to an animal at risk for or suffering from a reproductive disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective to prevent or ameliorate the disorder, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. In one embodiment, the reproductive disorder includes, but is not limited to, amenorrhea, an inability or reduced ability to ovulate, an inability to conceive, an inability or reduced ability to maintain a pregnancy, an inability or reduced ability to lactate, an inability or reduced ability to deliver a full-term offspring, and an inability or reduced ability to impregnate a female.

Yet another embodiment of the present invention relates to a method to control undesired body weight which is a side effect resulting from administration of a pharmaceutical compound, comprising administering to an animal at risk of or suffering from undesired body weight which is a side effect resulting from administration of a pharmaceutical compound, a therapeutic composition comprising a proopiomelanocortin (POMC) compound wherein the POMC compound is administered to the periphery of the animal in an amount effective to measurably decrease body weight or weight gain in the animal, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. In one embodiment, the pharmaceutical

compound includes, but is not limited to, valproic acid, lithium, tricyclic antidepressants, and selective serotonin reuptake inhibitors (SSRI).

Another embodiment of the present invention relates to a food composition that regulates the peripheral melanocortinergic and/or leptinergic pathways of energy homeostasis, comprising a proopiomelanocortin (POMC) compound. Preferably, the food composition is effective to measurably regulate body weight in the animal, and wherein delivery of the compound to the central nervous system of the animal is minimized.

Yet another embodiment of the present invention relates to a method to increase the body weight and/or mass in an animal having an eating disorder, comprising administering to the animal a therapeutic composition comprising a proopiomelanocortin (POMC) antagonist compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective to measurably increase body weight or reduce body weight loss in the animal, whereby administration of the compound minimizes delivery of the compound to the central nervous system of the animal. In one embodiment, the eating disorder is selected from the group consisting of anorexia and bulimia.

Another embodiment of the present invention relates to a method to identify compounds which regulate body weight in an animal, and particularly, compounds useful in any of the methods of the present invention as described herein. In a preferred embodiment, the present methods are useful for identifying homologues and mimetics of POMC compounds, for use in a therapeutic method of the present invention. Such a method includes screening a putative regulatory compound (i.e., a test compound) for its ability to stimulate lipolysis and/or to inhibit fatty acid uptake by adipocytes, and in particular, to control obesity. Such a method includes selecting compounds which preferentially bind to and/or activate peripheral melanocortin receptors as compared to central nervous system melanocortin receptors, and particularly, MC4-R. Such a method can be performed *in vitro* or *in vivo* (e.g., *in vivo* experiments can be performed using the POMC mutant mouse model of obesity of the present invention, and the compounds identified by such a method can be used in the method to treat obesity according to the present invention).

More particularly, one aspect of this method of the present invention is a method for identifying compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. Such a method includes the steps of: (a) contacting a putative regulatory compound with a cell which expresses a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting whether the putative regulatory compound increases the melanocortin receptor activity; (c) contacting the putative regulatory compound with a cell which expresses a melanocortin 4-receptor (MC4-R); and, (d) detecting whether the putative regulatory compound increases MC4-R activity. In this method, putative regulatory compounds that induce greater MC2-R activity and/or MC5-R activity as compared to MC4-R activity are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor of (a) and (b) is MC2-R. The step (b) of detecting can include, but is not limited to, measurement of melanocortin receptor transcription, measurement of melanocortin receptor translation, measurement of phosphorylation of melanocortin receptor, measurement of G protein activation, measurement of melanocortin receptor ligand binding activity, and/or measurement of melanocortin receptor translocation within a cell. In one embodiment, the cell of step (a) is an adipocyte, and wherein the step (b) of detecting is selected from the group consisting of measurement of melanocortin receptor transcription, measurement of melanocortin receptor translation, measurement of phosphorylation of melanocortin receptor, measurement of melanocortin receptor ligand binding activity, measurement of melanocortin receptor translocation within a cell, measurement of lipolysis by the cell and measurement of free fatty acid uptake by the cell. In another embodiment, the step (d) of detecting is selected from the group consisting of measurement of MC4-R transcription, measurement of MC4-R translation, measurement of phosphorylation of MC4-R, measurement of MC4-R ligand binding activity, and measurement of MC4-R translocation within a cell.

Another aspect of the invention relates to a method for identifying compounds that increase body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a cell which expresses a melanocortin receptor selected from

the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates the melanocortin receptor, in the presence and absence of a putative regulatory compound; and (b) detecting whether the putative regulatory compound inhibits the melanocortin receptor activity. In this embodiment, putative regulatory compounds that inhibit the melanocortin receptor activity are identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R. In another embodiment, the putative regulatory compound is further evaluated for its ability to regulate body weight in an *in vivo* model of body weight regulation, such by peripheral administration of the compound to the *pomc/pomc* mouse described herein. The POMC compound can include, but is not limited to a melanocortin compound, including α -MSH, β -MSH and γ -MSH. More particularly, a POMC compound can include any POMC compound described herein.

In another aspect, the method is a method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell which expresses a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting whether the putative regulatory compound binds to the melanocortin receptor; and, (c) administering compounds which bind to the melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of the test animal. In this aspect, putative regulatory compounds that bind to the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which regulate body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R. The test animal can be, for example, ~~but is not limited to, a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein the genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in the animal.~~

Yet another aspect of the method is a method for identifying compounds that increase body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a cell which expresses a melanocortin receptor selected from

the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates the melanocortin receptor, in the presence and absence of a putative regulatory compound; (b) detecting whether the POMC compound binds to the melanocortin receptor; (c) administering
5 compounds which bind to the melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of the test animal. In this aspect, putative regulatory compounds that bind to the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which increase body weight by regulating peripheral pathways of energy homeostasis. In
10 a preferred embodiment, the melanocortin receptor is MC2-R.

Another aspect of the method is a method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a melanocortin receptor selected
15 from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting expression of the reporter gene product; (c) contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a melanocortin 4-receptor (MC4-R); and, (d) detecting expression of the reporter gene product. In this aspect, putative
20 regulatory compounds that increase expression of the reporter gene product of (b) as compared to the reporter gene product of (d) are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

Yet another aspect of this method is a method for identifying compounds that
25 regulate body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell or cell lysate containing transcripts of a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); and, (b) detecting translational inhibition of the melanocortin receptor transcript. In this aspect,
30 putative regulatory compounds that inhibit the melanocortin receptor transcript are

identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

Another aspect of this method is a method for identifying compounds that regulate peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with an isolated adipocyte; and, (b) detecting putative regulatory compounds that bind to a melanocortin receptor on the adipocyte, wherein putative regulatory compounds that bind to melanocortin receptors on the adipocytes are identified as compounds that regulate body weight by regulating peripheral pathways of energy homeostasis. The step of detecting can further comprise detecting putative regulatory compounds which produce a result selected from the group consisting of stimulation of lipolysis in the adipocytes and inhibition of the uptake of fatty acids by the adipocytes, wherein putative regulatory compounds that bind to melanocortin receptors on the adipocytes and that produce the result are identified as compounds that regulate body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

Another embodiment of the present invention generally relates to a non-human animal model for studying and developing protocols for modifying the peripheral as well as the central melanocortinerbic pathways controlling body weight. In particular, the present invention relates to a genetically modified non-human animal comprising a genetic modification within at least one allele of its *Pomc* locus, wherein the genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in the animal. In one embodiment, the present invention relates to a POMC homozygous mutant mouse model. Such animal models are used for studying and developing protocols for modifying the peripheral as well as the central melanocortinerbic pathways controlling body weight in *Pomc* mutants, for studying and developing protocols for controlling other forms of weight dysregulation, and for determining which of the specific POMC compounds are most efficient at mediating the effects on weight loss or weight gain and on adrenal insufficiency.

More particularly, one embodiment of the present invention relates to a genetically modified non-human animal useful for studying peripheral and central pathways of energy homeostasis. The genetically modified non-human animal comprises a genetic

modification within at least one allele of its *Pomc* locus, wherein the genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in the animal (e.g., a heterozygous mutant animal). In one embodiment, the genetic modification includes, but is not limited to, a deletion, an insertion, a substitution and/or an inversion of nucleotides in the *Pomc* locus. The genetic modification can be a modification including or within exon 3 of the *Pomc* locus which results in a reduction in POMC peptide action, or a modification in a region of the *Pomc* locus other than exon 3 which results in a reduction in POMC peptide action (e.g., exon 1, exon 2 and/or a regulatory region of the *Pomc* locus). In a preferred embodiment, the genetic modification is a deletion of a nucleic acid sequence within at least one allele of the *Pomc* locus, wherein the deletion results in an reduction of expression of POMC peptides by the animal. In another embodiment, the animal comprises a genetic modification within two alleles (i.e., both alleles) of the *Pomc* locus, wherein the genetic modification results in an absence of POMC peptide action in the animal (e.g., a homozygous mutant animal). Preferably, the genetic modification is a deletion of a nucleic acid sequence within both alleles of the *Pomc* locus, wherein the deletion results in an absence of expression of POMC peptides by the animal.

In one embodiment of the present invention, the genetic modification is a deletion of a nucleic acid sequence comprising exon 3 of *Pomc*. In another embodiment, the genetic modification is a deletion of exon 3 of *Pomc*. In yet another embodiment, the genetic modification is a deletion of a portion of exon 3 of *Pomc* sufficient to reduce or prevent expression of POMC peptides by at least one allele and more preferably, by both alleles, of the *Pomc* locus of the animal. In further embodiments of the present invention, the genetically modified non-human animal is characterized by a phenotypic characteristic which includes, but is not limited to obesity, a defect in adrenal development, altered pigmentation, measurably increased serum leptin levels, increased food uptake, and/or measurably reduced serum levels of a hormone selected from the group of corticosterone, aldosterone and epinephrine, as compared to a wild-type sibling of the animal.

In one embodiment of the present invention, the genetically modified non-human animal is a mouse. In this embodiment, the genetic modification is preferably a deletion from the genome of a nucleic acid sequence comprising SEQ ID NO:7, although other

modifications as discussed above, which result in a reduction in the action of POMC peptides, are encompassed by the present invention.

Another embodiment of the present invention relates to a method to study the molecular and biochemical events associated with body weight gain and loss, and particularly, with such events that are associated with obesity. More particularly, such a method includes the steps of: (a) harvesting cells, tissues or body fluids from a genetically modified non-human animal of the present invention; and, (b) comparing the cells, tissues or body fluids from the genetically modified non-human animal to cells, tissues or body fluids from a wild-type sibling of the genetically modified non-human animal. In one embodiment, the step of comparing is performed by an assay selected from the group consisting of morphological examination of the cells, tissues or body fluids; histological examination of the cells, tissues or body fluids; evaluation of POMC peptide biological activity in the animal; evaluation of free fatty acid metabolism in the animal; evaluation of lipolysis and fatty acid sequestration in the animal; evaluation of weight gain or loss in the animal; evaluation of hormone levels in the animal; and, evaluation of blood biochemistry in the animal.

Yet another embodiment of the present invention relates to a method to identify POMC compounds, and particularly, homologues and mimetics, for use in regulating peripheral and central pathways of energy homeostasis. The method includes the steps of: (a) administering a compound to be evaluated to a genetically modified non-human animal which comprises a genetic modification within two (both) alleles of its *Pomc* locus, wherein the genetic modification results in an absence of POMC peptide action in the animal; and, (b) evaluating physiological and pathological changes in the genetically modified non-human animal as compared to a non-human animal selected from the group of: (i) a second genetically modified non-human animal comprising a genetic modification within at least one allele of its *pomc1* locus, wherein the genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in the animal; and (ii) a third non-human animal having a genome comprising a wild-type *pomc1* locus at two (i.e., both) alleles. Various compounds which can be evaluated include, but are not limited to POMC compounds, including a POMC peptide (i.e., a peptide encoded by the *Pomc* gene), a fragment of such a peptide (including both biologically active and inactive

fragments), a homologue of such a peptide, a mimetic (peptide or non-peptide) of such a peptide, a fusion protein comprising such a peptide, and any pharmaceutical salts of such a peptide, as well as any non-POMC peptide.

Yet another embodiment of the present invention relates to a method of producing
5 a genetically modified non-human animal useful for studying peripheral and central
pathways of energy homeostasis. Such a method includes the steps of: (a) introducing
into an embryonic stem cell of a non-human animal a targeting vector comprising a *Pomc*
locus containing a modification of a nucleic acid sequence sufficient to result in a
reduction in proopiomelanocortin (POMC) peptide action in the animal; and, (b) obtaining
10 progeny having the modification stably incorporated into their genome, wherein the
modification results in a reduction in expression of proopiomelanocortin (POMC) peptides
by the animal. In one embodiment, this method additionally includes the step of obtaining
progeny having the modification stably incorporated into their genome, wherein the
modification results in an *absence* of expression of POMC peptides by the animal. In a
15 preferred embodiment, the modification is a deletion in a nucleic acid sequence sufficient
to result in the reduction of POMC peptide action in the animal.

Another embodiment of the present invention is a genetically modified mouse
useful for studying peripheral and central pathways of energy homeostasis. The mouse
is produced by a method comprising the steps of: (a) isolating from a source of murine
20 genomic DNA a nucleic acid molecule comprising SEQ ID NO:7; (b) modifying a nucleic
acid sequence comprising SEQ ID NO:7 in the nucleic acid molecule to form a genetically
modified nucleic acid molecule; (c) inserting a selectable marker into the genetically
modified nucleic acid molecule to create a targeting vector; (d) transfecting the targeting
vector into embryonic stem cells; (e) selecting embryonic stem cells from step (d) which
25 have incorporated the targeting vector at a target locus comprising SEQ ID NO:7 by
homologous recombination; (f) inserting the embryonic stem cells comprising the targeting
vector into non-human animal blastocysts; and, (g) impregnating a female surrogate with
the non-human animal blastocysts to produce the genetically modified mouse. In a
preferred embodiment, the modification of step (b) is a deletion in the nucleic acid
30 sequence comprising SEQ ID NO:7.

DETAILED DESCRIPTION OF THE INVENTION

The present invention generally relates to compositions and methods for regulating body weight in an animal and for treating or preventing conditions related thereto, and particularly, health-compromising conditions related thereto, as well as to methods to
5 identify compounds useful in such methods. According to the present invention, to "control" or "regulate" body weight, can refer to reducing body weight, increasing body weight, reducing the rate of weight gain, or reducing the rate of weight loss, and includes actively maintaining, or not significantly changing body weight (e.g., against external or internal influences which may otherwise increase or decrease body weight).

10 One embodiment of the present invention relates to regulating body weight by administering to the periphery of an animal a proopiomelanocortin (POMC) compound, which can include a POMC peptide, a fragment thereof, a homologue thereof, a peptide or non-peptide mimetic thereof, a fusion protein including such peptide, a pharmaceutically acceptable salt thereof, or a recombinant nucleic acid molecule encoding
15 such a POMC peptide, fragment, homologue, peptide mimetic, or fusion protein thereof, and includes both POMC agonists and antagonists. In a preferred embodiment, the POMC compound is a melanocyte stimulating hormone (MSH) compound. The POMC compound is administered in an amount effective to measurably regulate body weight in the animal, whereby administration of the compound minimizes delivery of the compound
20 to the central nervous system of the animal. These aspects of the invention are discussed in detail below.

In one aspect, the present invention relates to reducing body weight and/or reducing weight gain in an animal, and more particularly, to treating or ameliorating obesity in patients at risk for or suffering from obesity. In another aspect, the present
25 invention is directed to a method and compound for treating an animal that is unable to ~~gain or retain weight (e.g., an animal with a wasting syndrome).~~ Such a method is effective to increase body weight and/or mass, or to reduce weight and/or mass loss, or to improve conditions associated with or caused by undesirably low (e.g., unhealthy) body weight and/or mass. In the former aspect, discussed in detail below, the method
30 comprises administering to an animal a POMC compound having POMC agonist biological activity, including both naturally occurring POMC peptides and homologues

or mimetics thereof. In the latter aspect, which is also discussed in detail below, the method comprises administering to an animal that is at risk for developing or has low body weight and/or a detrimental condition related thereto, a POMC antagonist compound, and preferably, a homologue or mimetic of a POMC peptide. Such a compound has
5 antagonistic biological activity (i.e., an antagonist of the prototype peptide) as compared to the naturally occurring POMC peptide (i.e., prototype) upon which the homologue or mimetic is based. The POMC compound is administered peripherally in an amount effective to induce a measurable decrease or increase in the body weight and/or mass of the animal, or minimally, to increase the rate of gain or reduce the rate of loss of body
10 weight and/or mass in the animal. The POMC compound can be administered in conjunction with one or more other compounds that are useful for regulating body weight and/or mass, and particularly, for decreasing or increasing body weight in an animal. Preferably, decreasing or increasing body weight and/or mass and/or increasing or reducing the rate of weight and/or mass loss/gain in an animal is effective for treating or
15 ameliorating undesired and/or health-compromising conditions associated with low or high body weight, such conditions being discussed in detail herein.

More particularly, the present invention relates to the inventors' discovery that administration of a proopiomelanocortin (POMC) peptide agonist to an animal suffering from obesity reduces obesity in the animal. Included in the invention is a method for
20 modifying the peripheral melanocortinergetic pathways for controlling obesity in patients at risk of, or suffering from, obesity and/or conditions associated therewith, by administering an effective amount of circulating melanocyte stimulating hormone (MSH) or analogs (e.g., homologues or mimetics) thereof, alone or in combination with leptin or other body weight regulating drugs. Additionally, the present invention relates to a
25 proopiomelanocortin null mutant mouse model for studying the human proopiomelanocortin null syndrome.

As discussed in the background section, prior to the present invention, findings from several lines of investigations have placed proopiomelanocortin (POMC) and the peptides derived from it at a pivotal position in the *central* pathways for energy
30 homeostasis (Lu et al., 1994, *supra*, Graham et al., 1997, *supra*, Ollmann et al., 1997, *supra*, Huzar et al., 1997, *supra*, Fan et al., 1997, *supra*, PCT Publication WO 97/47316,

supra, U.S. Patent No. 5,908,609, *supra* and U.S. Patent No. 5,932,779, *supra*). However, while other investigators have focused on this recognition that proopiomelanocortins (POMC) are involved in the central pathways for energy homeostasis (i.e., regulation through the central nervous system and brain receptors), the present inventors were the first to appreciate the role of POMC peptides in the regulation of *peripheral* pathways of energy homeostasis (i.e., adipocyte regulation through inhibition of free fatty acid uptake and/or stimulation of lipolysis). The present inventors discovered the role of POMC peptides in the regulation of peripheral energy homeostasis through the development and study of mice with a targeted deletion of the POMC gene and by the administration of an MSH agonist to such mice.

The data from previous investigators which suggested a central nervous system (hypothalamic) effect of melanocortins on appetite, and the present inventors' data which demonstrates a peripheral action of melanocortins on fatty acid metabolism, have led the present inventors to propose the following mechanism for the novel method of the present invention. Without being bound by theory, the present inventors believe that the method of the present invention, while it may have some impact on the central melanocortinergetic pathways of energy homeostasis, is primarily effective for regulating adipocyte/fatty acid metabolism. In support of this belief, it is noted that the molar concentration of a melanocortin agonist that would be necessary to effect a transient decrease in food intake (i.e., via the central nervous system and the melanocortin 4-receptor) is *one hundred-fold higher* than that required to accomplish weight reduction in obese mice or to prevent weight gain in a mouse that is genetically predisposed to obesity. Also without being bound by theory, the present inventors believe that under some physiological conditions, an organism is compelled both to suppress appetite and to metabolize fat stores from peripheral adipose tissue. Secretion of melanocortins in the hypothalamus serves to suppress appetite and, after diffusion to the periphery, melanocortins from the hypothalamus, and possibly elsewhere, stimulate lipolysis from adipocytes. It is significant that the amount of melanocortin agonist necessary to effect a decrease in appetite when applied directly to the hypothalamus is equivalent to the amount necessary to effect a decrease in fatty acid accumulation when applied peripherally. In the normal course of events (i.e., in the endogenous system of a normal animal), melanocortins are produced

in the hypothalamus and then diffuse to the periphery. It follows that cells in the hypothalamus should be less sensitive to melanocortins and cells in the periphery more sensitive. Again, this is consistent with the present inventors' findings that the amount of peripherally administered melanocortin agonist needed to effect body weight homeostasis is at least two orders of magnitude lower than that required to effect a change in appetite.

The discovery by the present inventors of the present methods and compositions provides particular advantages compared to previously described methods of weight control, in that when the POMC compounds as described herein are applied peripherally according to the method of the present invention, rather than produced centrally, the effects of the compound will be substantially restricted to the periphery, since the central nervous system concentrations will not approach those necessary to have a significant impact on hyperphagia. Thus, the method of the present invention takes advantage of the differential sensitivities of the central nervous system and peripheral tissues to POMC compounds, such as melanocortins. By applying a POMC compound as described herein peripherally, when the naturally occurring form of such compound is normally produced centrally, peripheral effects are stimulated while central nervous system effects are mitigated. For example, a change in the metabolism of fatty acids may be affected without direct alteration of the appetite of the patient.

Moreover, prior to the present invention, without the discovery by the present inventors that POMC compounds administered peripherally will act peripherally to regulate body weight, it would have been inconceivable to consider using a POMC peptide to control body weight in humans, because, as mentioned above, the concentrations of POMC compound that would be necessary to affect the central nervous system (the only mechanism known prior to the present invention) by peripheral administration are physiologically unreasonable, if not impossible. Furthermore, to administer such compounds directly to the central nervous system would be unthinkable as a therapeutic method for use in humans. Therefore, the present inventors' discovery represents a previously unappreciated frontier in body weight control.

In addition, by taking advantage of the scientific knowledge gained from the discovery regarding weight loss, the present inventors have also discovered a method for modifying the peripheral melanocortinerbic pathways for *increasing* body weight or body

mass in patients at risk of, or suffering from, undesirable and/or unhealthy weight and/or mass loss, by administering an effective amount of circulating POMC analogs (e.g., homologues or mimetics) having POMC antagonist action, and particularly, melanocyte stimulating hormone (MSH) analog antagonists, alone or in combination with other body weight regulating drugs (e.g., anabolic steroids, growth hormone, erythropoietin, cytokines, and anti-cytokine agents).

According to the present invention, "undesirable" gain of body weight and/or mass refers to any gain of body weight or body mass (i.e., gain of body mass can occur in the absence of measurable or significant weight gain) in an individual, as compared to a prior weight or body mass of that individual, where such weight and/or mass gain is unintended, unexpected, and/or unhealthy, as determined by the individual or by a medical professional evaluating such individual. Similarly, "unhealthy" or "health-compromising" weight and/or mass gain is referred to herein as any gain of body weight or body mass which is either deemed by the individual or medical professional to be unhealthy, or which results in a symptom that can be associated with poor health, such as diabetes or cardiovascular conditions. Accordingly, "undesirable" loss of body weight and/or mass refers to any loss of body weight or body mass (i.e., loss of body mass can occur in the absence of measurable or significant weight gain) in an individual, as compared to a prior weight or body mass of that individual, where such weight and/or mass loss is unintended, unexpected, and/or unhealthy, as determined by the individual or by a medical professional evaluating such individual. Similarly, "unhealthy" or "health-compromising" weight and/or mass loss is referred to herein as any loss of body weight or body mass which is either deemed by the individual or medical professional to be unhealthy, or which results in a symptom that can be associated with poor health, such as heart problems, weakened immune function, lack of strength or energy, and/or depression.

The method of the present invention is useful for treating any condition or disorder that is characterized by or associated with undesirable or unhealthy body weight or body mass gain or loss. With regard to undesirable or unhealthy body weight or body mass gain, such conditions include, but are not limited to non-insulin dependent diabetes mellitus (NIDDM), cardiovascular disease, cancer, hypertension, osteoarthritis, stroke, respiratory problems and gall bladder disease. Other conditions associated with

undesirable or unhealthy body weight or body mass gain, such conditions include, but are not limited to depression, mood disorders, reproductive dysfunction, and pharmaceutical non-compliance. With regard to undesirable or unhealthy body weight or body mass gain, such conditions, include, but are not limited to wasting syndromes (e.g., wasting disease, cachexia and sarcopenia) and conditions associated with such syndromes, including, but not limited to, aging, cancer, AIDS (or HIV infection), extensive surgery, chronic infections, immunologic diseases, hyperthyroidism, extraintestinal Crohn's disease, psychogenic disease, chronic heart failure or other severe trauma. According to the present invention, the phrase "wasting syndrome" is used generally to refer to any condition characterized by undesirable weight and/or body mass loss. The term "cachexia" is used to refer to a metabolic and sometimes, eating disorder, which is additionally characterized by hypermetabolism and hypercatabolism, and which results in a loss of fat-free mass, and particularly, body cell mass. "Sarcopenia" refers to yet another such disorder which is typically characterized by loss of muscle mass. The term "wasting disease" is used to more specifically refer to loss of body weight, including both the fat and the fat-free compartments, which is typically found in the elderly, or in late stage cachexia or sarcopenia.

In the method of the present invention, therapeutic compositions can be administered to any animal, and preferably, to any member of the Vertebrate class, Mammalia, including, without limitation, primates, rodents, livestock and domestic pets. Livestock include mammals to be consumed or that produce useful products (e.g., sheep for wool production). Preferred mammals to treat include humans. According to the present invention, the term "patient" or "individual" is used to describe both human and non-human animals. In a preferred embodiment, the present method is used for treating obese patients having abnormal (e.g., high or low as compared to a substantially healthy individual of medically normal body weight and/or mass) endogenous levels of circulating MSH or leptin or both.

Proopiomelanocortin (POMC) peptides, including the melanocortins: adrenocorticotrophin (ACTH); α -, β - and γ -melanocyte stimulating hormones (MSH); and the opioid receptor ligand β -endorphin, have a diverse array of biological activities, including roles in pigmentation, adrenocortical function, regulation of energy stores, and

the immune, central nervous and peripheral circulation system (Smith, A.I. et al., *Endocr Rev* 9, 159-179 (1988); König, "Peptide and protein hormones: structure, regulation, activity, a reference manual" (Weinheim; NY 1993)).

5 The POMC mutant mouse developed by the present inventors and described herein is a model of obesity that was engineered to carry an autosomal recessive null allele of the POMC gene. This mutant lacks all of the peptide hormones encoded by this locus. The present inventors have discovered that mice lacking the POMC peptides have obesity, a defect in adrenal development, and altered pigmentation. This phenotype is similar to the recently identified human POMC mutants (Krude, et al., 1998, *Nat Genet* 19, 155-7). In addition to a dysregulation of fat metabolism, the POMC-deficient mice showed increased food intake. When the inventors treated the mutant mice peripherally with a stable α -MSH agonist, these mice lost over 40% of their excess weight after two weeks, whereas wildtype non-obese mice did not lose significant weight. The present inventors have shown that the weight changes in POMC null mice are not simply regulated through feeding behavior, but rather through both central and peripheral actions of melanocortins. Based on *in vivo* experiments described herein, the present inventors have shown MSH to be an adiposity regulating hormone. Peripheral treatment of *pomc/pomc* and *ob/ob* mutants with an MSH mimetic ameliorated obesity, but did not significantly diminish weight in normal mice. Consequently, these results indicate that certain subpopulations of obese patients will be particularly amenable to treatment with MSH and homologues and mimetics thereof, although the present invention encompasses the use of POMC compounds to treat any patient with undesired body weight. Pharmacological agents which are biologically active and mimic the activity of MSH are therefore useful for treating obese patients, particularly those with abnormal levels of circulating MSH. The present inventors are the first to appreciate that the POMC peptides have both a central and peripheral effect on feeding behavior and on body weight regulation. Similarly, pharmacological agents which are biologically active and antagonize the activity of endogenous MSH are therefore useful for treating patients with undesired weight and/or mass loss conditions, such as cachexia.

30 Furthermore, the present inventors have demonstrated that the POMC null mutant mouse is a model for studying the human POMC null syndrome. In addition to being a

mouse model for the human POMC deficiency, the POMC mutant mouse is a valuable addition to the growing number of murine obesity models, aiding in the dissection of the mechanisms of energy homeostasis, centrally and peripherally, as well as in exploring therapeutic regimens for the human POMC deficient patients and possibly for other, multigenic-multifactorial forms of human obesity. The anti-obesity effects of MSH indicate a therapeutic use in POMC-deficient as well as other forms of obesity.

One embodiment of the present invention relates to a method to regulate body weight in an animal (e.g., a human patient). Such a method includes the step of administering to the animal a therapeutic composition that includes a POMC compound.

According to the present invention, the phrase "POMC compound" encompasses any of the following compounds: a POMC peptide (i.e., a peptide encoded by the POMC gene), a fragment of such a peptide (including both biologically active and inactive fragments), a homologue of such a peptide, a mimetic (peptide or non-peptide) of such a peptide, a fusion protein comprising such a peptide, and any pharmaceutical salts of such a peptide.

In addition, peptides useful in the present invention may exist, particularly when formulated, as dimers, trimers, tetramers, and other multimers. Such multimers are included within the scope of the present invention. As used herein, the term "analog", as used in connection with a POMC peptide according to the present invention, refers generically to any homologue or mimetic (peptide or non-peptide) of a POMC peptide.

Analogues can include both agonists and antagonists of the prototype POMC peptide, unless specifically used in connection with the term "antagonist" or "agonist". The phrase "POMC agonist compound" or "POMC agonist" refers to any fragment, homologue or mimetic (peptide or non-peptide) of a POMC peptide (i.e., a naturally occurring or prototype) which is characterized by its ability to agonize (e.g., stimulate, induce, increase, enhance) the biological activity of the naturally occurring POMC peptide (e.g., interaction/binding with and/or activation of a POMC receptor). The phrase "POMC antagonist compound" or "POMC antagonist" refers to any fragment, homologue or mimetic (peptide or non-peptide) of a POMC peptide (i.e., naturally occurring or prototype) which is characterized by its ability to antagonize (e.g., inhibit, block, decrease, compete against) the biological activity of the naturally occurring POMC peptide (e.g., interaction/binding with and/or activation of a POMC receptor). Terms used herein in

connection with POMC genes and proteins (e.g., "compound", "analog", "homologue", "mimetic") can be similarly used with specific POMC genes and proteins (e.g., an MSH peptide, an MSH compound, an MSH analog, etc.). Homologues and mimetics are described in detail below. In one embodiment of the present invention, a POMC compound is an isolated nucleic acid molecule that encodes a POMC peptide, a peptide analog thereof, or a fusion protein comprising such a peptide. In addition, peptides useful in the present invention may exist, particularly when formulated, as dimers, trimers, tetramers, and other multimers. Such multimers are included within the scope of the present invention.

For embodiments of the present invention related to decreasing body weight and/or decreasing the rate of weight gain, preferably, POMC compounds according to the present invention are any compound having one or more of the following properties or identifying characteristics: (1) an ability to bind to a POMC peptide receptor, and particularly, to a POMC receptor that is expressed in peripheral (as opposed to central nervous system) tissues; and, (2) an ability to stimulate lipolysis and/or to inhibit the uptake of fatty acids by adipocytes. Particularly preferred POMC compounds for use in the present method include homologues and mimetics of naturally occurring POMC peptides which have substantially similar, or even more preferably, enhanced, properties or identifying characteristics as compared to the naturally occurring (i.e., prototype) POMC peptide (e.g., agonists). Such properties or identifying characteristics include: (1) enhanced ability to bind to a POMC peptide receptor, and particularly, to a POMC receptor that is expressed in peripheral (as opposed to central nervous system) tissues; (2) enhanced serum half-life (i.e., enhanced stability under physiological conditions); and/or (3) enhanced ability to stimulate lipolysis and/or to inhibit the uptake of fatty acids by adipocytes.

For embodiments of the present invention related to increasing body weight and/or decreasing the rate of weight loss, preferably, POMC compounds according to the present invention are any compound having one or more of the following properties or identifying characteristics: (1) an ability to bind to a POMC peptide receptor, and particularly, to a POMC receptor that is expressed in peripheral (as opposed to central nervous system) tissues; and, (2) an ability to inhibit lipolysis and/or to increase the uptake

of fatty acids by adipocytes. Particularly preferred POMC compounds for use in this embodiment include homologues or mimetics of a POMC peptide which block or inhibit the action of a naturally occurring POMC-peptide (i.e., an antagonist), such that a patient's ability to gain weight and/or mass or avoid undesirable weight and/or mass loss is improved (i.e., a POMC antagonist compound). The desirable properties of a POMC antagonist compound include a decreased ability to stimulate lipolysis and/or to inhibit the uptake of fatty acids by adipocytes (or an ability to inhibit lipolysis and/or to stimulate the uptake of fatty acids by adipocytes), while serum half-life and receptor binding abilities (for blocking, but not activating the receptor) are preferably substantially similar or enhanced compared to the naturally occurring peptide.

Peripheral adipocytes are known to express two different melanocortin receptors, melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R). Without being bound by theory, the present inventors believe that of these two peripheral melanocortin receptors, the MC2-R is the most important in controlling the peripheral pathways of energy homeostasis, although both receptors may play roles in this process. Prior to the present invention, other investigators had shown relatively little interest in the properties of the MC2-R, however, the present inventors have provided evidence herein that this receptor, alone and/or in combination with the MC5-R, plays a significant role in the regulation of peripheral metabolic efficiency. Therefore, in a preferred embodiment of the present invention, a POMC compound of the present invention has an ability to bind to (e.g., interact with) the melanocortin 2-receptor and/or the melanocortin 5-receptor, with the melanocortin 2-receptor being more preferred. With regard to the embodiment for decreasing body weight in an animal, preferably, a POMC compound has an ability to activate or increase the activation of the melanocortin 2-receptor and/or the melanocortin 5-receptor. With regard to the embodiment for increasing body weight in an animal, preferably, a POMC compound has an ability to block activation of, inhibit activation of or decrease activation of the melanocortin 2-receptor and/or the melanocortin 5-receptor (i.e., a POMC antagonist, which could also be referred to as an antagonist of a POMC receptor).

As discussed above, it is an advantage of the method of the present invention that the effect of the POMC peptide administration is substantially restricted to the periphery,

so that body weight and/or mass of an animal can be regulated in the absence of significantly affecting the appetite of the animal. As the present inventors have discovered, it is not necessary to have a significant, if any, primary effect on appetite to affect weight loss in an animal. As will be discussed in detail below, this advantage of the present invention is most easily achieved by administration of the POMC compound peripherally (i.e., by a route that does not deliver the compound directly or preferentially to the central nervous system and especially the brain). When a POMC compound is administered peripherally in an amount effective to act on peripheral receptors while mitigating effects on central receptors (e.g., the molar concentration of a melanocortin agonist that would be necessary to effect a transient decrease in food intake via the central nervous system and the melanocortin 4-receptor when delivered peripherally is at least *one hundred-fold higher* than that required to accomplish weight reduction via peripheral receptors, and is likely to be toxic), no additional modification of the POMC peptide is necessary. However, in one embodiment of the invention, the potential for effects on the central nervous system can be further minimized by selecting POMC compounds that preferentially bind to and/or activate/inhibit the peripheral melanocortin receptors as compared to the central melanocortin receptors, and particularly melanocortin 4-receptor (MC4-R). In one embodiment of the present invention, the administration of the POMC compound is insufficient to cause a statistically significant change in the appetite of the animal as compared to the appetite of the animal prior to administration of the compound.

In one embodiment, wherein decrease in body weight and/or mass is the goal, a preferred POMC compound: (1) binds to an MC2-R and/or MC5-R with a higher affinity (or avidity) than to an MC4-R; and/or (2) activates an MC2-R and/or MC5-R to a greater degree or preferentially as compared to an MC4-R. In another embodiment, a preferred POMC compound binds to and/or activates an MC2-R and/or an MC5-R, and does not bind to, binds with very low affinity to (i.e., whereby the receptor is not activated or is not activated to a degree to provide a significant biological activity), and/or does not substantially activate, any other melanocortin receptor under physiological conditions. In yet another embodiment, a preferred POMC compound does not bind to, binds with very low affinity to, and/or does not substantially activate an MC4-R under physiological conditions. In another embodiment, wherein an increase in body weight and/or mass is

the goal, although the POMC compound preferably binds to an MC2-R and/or MC5-R with a higher affinity (or avidity) than to an MC4-R in order to minimize central nervous system effects, the POMC compound (e.g., an antagonist), preferably inhibits the activation of an MC2-R and/or MC5-R. In addition to POMC antagonist compounds as described above, an antibody that binds to and blocks the receptor and/or a soluble MC2-R or MC5-R that competes with the endogenous receptor can be administered.

Preferably, a POMC compound that binds to an MC2-R or an MC5-R binds to such receptors with at least a 10 fold greater affinity or avidity as compared to binding to an MC4-R, and more preferably, at least a 100 fold greater affinity or avidity, and more preferably, at least a 1000 fold greater affinity or avidity and even more preferably, at least a 10,000 fold greater affinity or avidity as compared to binding of the same compound to an MC4-R. A POMC compound useful for body weight loss or decrease in weight gain (including prevention of weight gain, or maintenance of weight) preferably induces or increases the activity of an MC2-R and/or an MC5-R at least about 10 fold more as compared to the activity of an MC4-R contacted with the same compound, and preferably, at least about 100 fold more, and more preferably, at least about 1000 fold more, and even more preferably, at least about 10,000 fold more as compared to the activity of an MC4-R contacted with the same compound.

In a preferred embodiment, the POMC compound can include any peptide that has an amino acid sequence which includes the amino acid sequence represented herein by SEQ ID NO:1 (EHFRW), or a homologue or mimetic thereof, which, when administered in an effective manner to a patient, has the ability to measurably regulate body weight in such patient. Peptides which have an amino acid sequence that includes SEQ ID NO:1 preferably also have one or more of the identifying characteristics of a POMC compound as described above.

In another embodiment, a preferred POMC compound includes, but is not limited to, a melanocortin and/or a lipocortin, fragments of such peptides, homologues of such peptides, mimetics (peptide or non-peptide) of such peptides, fusion proteins comprising such peptides, and any pharmaceutical salts of such peptides. Melanocortins include, but are not limited to: adrenocorticotrophin (ACTH), α -melanocyte stimulating hormone (α -MSH), β -melanocyte stimulating hormone (β -MSH) and γ -melanocyte stimulating

hormone (γ -MSH); and β -endorphin. Preferred melanocortins include melanocyte stimulating hormones (MSH), fragments of such peptides, homologues of such peptides, mimetics (peptide or non-peptide) of such peptides, fusion proteins comprising such peptides, and any pharmaceutical salts of such peptides. Particularly preferred MSH

5 peptides include α -MSH, β -MSH and γ -MSH, fragments of such peptides, homologues of such peptides, mimetics (peptide or non-peptide) of such peptides, fusion proteins comprising such peptides, and any pharmaceutical salts of such peptides.

The nucleic acid and amino acid sequences for the naturally occurring POMC peptides in a large variety of animals (i.e., human, mouse, rat, rabbit, bovine, ovine,

10 macaque, amphibian, etc.) are known in the art. Such sequences can be found, for example, in a protein or nucleic acid database such as GenBank. GenBank accession numbers for such POMC peptide (i.e., amino acid) sequences include, but are not limited to: Accession Nos. NP_000930 or CAA24754 (Homo sapiens); Accession No. P06297 (rabbit); Accession No. P01194 (rat); Accession No. P01193 (mouse); Accession No.

15 P01191 (sheep); Accession No. P01190 (bovine); and Accession No. CTMKP (pig-tailed macaque). GenBank accession numbers for such POMC nucleic acid sequences include, but are not limited to: Accession No. NM_000939 (Homo sapiens); Accession No. AH005319 (mouse); Accession Nos. J00016, J00019, J00021 (bovine); Accession No. S73519 (swine); S57982 (ovine); and Accession No. AH002232 (rat).

20 The amino acid sequence of human α -MSH is:

Ac-Ser-Tyr-Ser-Met-Glu-His-Phe-Arg-Trp-Gly-Lys-Pro-Val-NH₂;

and is represented herein by SEQ ID NO:2. It should be noted that since amino acid sequencing and nucleic acid sequencing technologies are not entirely error-free, any sequences presented or referenced herein, at best, represent apparent sequences of POMC

25 peptides, homologues, peptide mimetics, and nucleic acid sequences encoding such peptides, useful in the present invention.

As discussed above, particularly preferred POMC compounds for use in decreasing body weight according to the present invention are homologues or mimetics of POMC peptides, also referred to herein collectively as analogs of POMC peptides, which have

30 enhanced properties as compared to the naturally occurring POMC peptide, such properties including: (1) enhanced ability to bind to a POMC peptide receptor, and

particularly, to a POMC receptor that is expressed in peripheral (as opposed to central nervous system) tissues; (2) enhanced serum half-life (i.e., enhanced stability under physiological conditions); and/or (3) enhanced ability to stimulate lipolysis and/or to inhibit the uptake of fatty acids by adipocytes. Particularly preferred POMC antagonists
5 for use in increasing body weight according to the present invention are antagonistic homologues or mimetics of POMC peptides, also referred to herein collectively as antagonist analogs of POMC peptides, which have antagonistic properties to the naturally occurring POMC peptides, such properties including: (1) ability to bind to a POMC peptide receptor that is expressed in peripheral (as opposed to central nervous system)
10 tissues, and particularly, to block the binding of a naturally occurring POMC peptide to the receptor and/or to deliver a negative signal to the POMC receptor; (2) enhanced serum half-life (i.e., enhanced stability under physiological conditions); and/or (3) decreased ability to stimulate lipolysis and/or to inhibit the uptake of fatty acids by adipocytes or an ability to inhibit lipolysis and/or to stimulate the uptake of fatty acids by
15 adipocytes.

As used herein, the term "homologue" is used to refer to a peptide which differs from a naturally occurring peptide (i.e., the "prototype") by minor modifications to the naturally occurring peptide, but which maintains the basic peptide and side chain structure of the naturally occurring form. Such changes include, but are not limited to: changes in
20 one or a few amino acid side chains; changes in one or a few amino acids, including deletions (e.g., a truncated version of the peptide) insertions and/or substitutions; changes in stereochemistry of one or a few atoms; and/or minor derivatizations, including but not limited to: methylation, glycosylation, phosphorylation, acetylation, myristoylation, prenylation, palmitation, amidation and/or addition of glycosylphosphatidyl inositol.
25 Preferably, a homologue has either enhanced or substantially similar properties compared to the naturally occurring POMC peptide as discussed above (i.e., agonists), although peptides with diminished properties (i.e., antagonists) are also encompassed by certain embodiments of the present invention. Preferred fragments include any truncated or internal fragment of a naturally occurring POMC peptide which may or may not be
30 additionally modified as described herein for homologues and/or mimetics. In one embodiment, a preferred POMC fragment is a fragment of MSH, and more preferably, an

MSH fragment including amino acid positions 4-9, 4-10 or 4-11 of naturally occurring MSH. Such fragments, including analogs of such fragments, are discussed in detail below. In one embodiment, a homologue of a POMC peptide comprises an amino acid sequence comprising at least about 4, and more preferably at least about 8 and more preferably at least about 16 contiguous amino acid residues of an amino acid sequence of a naturally occurring (i.e., wild-type) POMC peptide. In another embodiment, a POMC peptide homologue is encoded by a nucleic acid sequence comprising at least about 12, and more preferably at least about 24, and even more preferably at least about 48 contiguous nucleotides of a nucleic acid sequence encoding a naturally occurring POMC peptide.

POMC homologues can be the result of natural allelic variation or natural mutation. A naturally occurring allelic variant of a nucleic acid encoding POMC peptide (or a protein comprising a POMC peptide) is a gene that occurs at essentially the same locus (or loci) in the genome as the gene which encodes such POMC peptide, but which, due to natural variations caused by, for example, mutation or recombination, has a similar but not identical sequence. Allelic variants typically encode proteins having similar activity to that of the protein encoded by the gene to which they are being compared. One class of allelic variants can encode the same protein but have different nucleic acid sequences due to the degeneracy of the genetic code. Allelic variants can also comprise alterations in the 5' or 3' untranslated regions of the gene (e.g., in regulatory control regions). Allelic variants are well known to those skilled in the art.

Homologues can be produced using techniques known in the art for the production of proteins including, but not limited to, direct modifications to the isolated, naturally occurring protein, direct protein synthesis, or modifications to the nucleic acid sequence encoding the protein using, for example, classic or recombinant DNA techniques to effect random or targeted mutagenesis.

As used herein, the term "mimetic" is used to refer to any peptide or non-peptide compound that is able to mimic the biological action of a naturally occurring peptide, often because the mimetic has a basic structure that mimics the basic structure of the naturally occurring peptide and/or has the salient biological properties of the naturally occurring peptide. Mimetics can include, but are not limited to: peptides that have substantial modifications from the prototype such as no side chain similarity with the

naturally occurring peptide (such modifications, for example, may decrease its susceptibility to degradation); anti-idiotypic and/or catalytic antibodies, or fragments thereof; non-proteinaceous portions of an isolated protein (e.g., carbohydrate structures); or synthetic or natural organic molecules, including nucleic acids and drugs identified through combinatorial chemistry, for example.

Such mimetics can be designed, selected and/or otherwise identified using a variety of methods known in the art. Various methods of drug design, useful to design mimetics or other therapeutic compounds useful in the present invention are disclosed in Maulik et al., 1997, *Molecular Biotechnology: Therapeutic Applications and Strategies*, Wiley-Liss, Inc., which is incorporated herein by reference in its entirety. A POMC mimetic can be obtained, for example, from molecular diversity strategies (a combination of related strategies allowing the rapid construction of large, chemically diverse molecule libraries), libraries of natural or synthetic compounds, in particular from chemical or combinatorial libraries (i.e., libraries of compounds that differ in sequence or size but that have the similar building blocks) or by rational, directed or random drug design. See for example, Maulik et al., *supra*.

In a molecular diversity strategy, large compound libraries are synthesized, for example, from peptides, oligonucleotides, carbohydrates and/or synthetic organic molecules, using biological, enzymatic and/or chemical approaches. The critical parameters in developing a molecular diversity strategy include subunit diversity, molecular size, and library diversity. The general goal of screening such libraries is to utilize sequential application of combinatorial selection to obtain high-affinity ligands for a desired target, and then to optimize the lead molecules by either random or directed design strategies. Methods of molecular diversity are described in detail in Maulik, et al., *ibid*.

Maulik et al. also disclose, for example, methods of directed design, in which the user directs the process of creating novel molecules from a fragment library of appropriately selected fragments; random design, in which the user uses a genetic or other algorithm to randomly mutate fragments and their combinations while simultaneously applying a selection criterion to evaluate the fitness of candidate ligands; and a grid-based approach in which the user calculates the interaction energy between three dimensional

receptor structures and small fragment probes, followed by linking together of favorable probe sites.

Preferred POMC analogs (homologues or mimetics) for use in the method of the present invention include POMC analogs of the melanocortins. Particularly preferred POMC analogs for use in the method of the present invention include analogs of MSH proteins (peptides). Numerous analogs (homologues and mimetics) of POMC peptides, and particularly, of melanocortins, have been previously described in the art, and all are intended to be encompassed for use in the method of the present invention. For example, such analogs are disclosed in Hadley et al., 1986, " α -Melanotropin analogs for Biomedical Applications", Neural and Endocrine Peptides and Receptors, T.W. Moody, ed., Plenum Publ. Corp., NY, pp. 45-56; U.S. Patent No. 4,649,191 to Hruby, U.S. Patent No. 4,918,055 to Hruby et al., U.S. Patent No. 5,674,839 to Hruby et al., U.S. Patent No. 5,683,981 to Hadley et al., U.S. Patent No. 5,714,576 to Hruby et al., and U.S. Patent No. 5,731,408 to Hruby et al., each of which is incorporated herein by reference in its entirety, particularly with regard to the structures of analogs of melanocortins and especially, MSH analogs, disclosed therein, as well as to the methods of producing such analogs. An MSH analog suitable for use in the method of the present invention is exemplified in Examples 2-5 (i.e., [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH, with the Cys residues being joined by a disulfide bond), although it will be apparent to those of skill in the art that the present invention is not limited to this particular MSH analog.

Preferred MSH analogs include, but are not limited to, the following analogs:

(a) cyclic and linear α -MSH fragment analogs of the core sequence of α -MSH, Met⁴-Glu⁵-His⁶-Phe⁷-Arg⁸-Trp⁹-Gly¹⁰ (positions 4-10 of SEQ ID NO:2), having modifications including but not limited to: (1) replacement of Met⁴ with Nle; (2) replacement of L-Phe⁷ with D-Phe⁷; (3) cyclization between positions 4 and 10; and/or (4) presence of Lys¹¹ in analog at position 10 (See U.S. Patent Nos. 5,674,839 and 5,714,576 to Hruby et al., *supra*);

(b) linear and cyclic analogs of α -MSH having the general formula:

Ac-[Nle⁴, X_{aa}⁵, His⁶, X_{aa}⁷, Arg⁸, Trp⁹, X_{aa}¹⁰]-NH₂ (SEQ ID NO:3)

wherein X_{aa}⁵ is either Glu or Asp, X_{aa}⁷ is Phe or D-Phe and X_{aa}¹⁰ is a dibasic amino acid, lysine, ornithine, 2,4,-diaminobutyric acid, or 2,3 diaminopropionic acid (Dpr); and,

wherein cyclization is between positions 4 and 10 (See U.S. Patent Nos. 5,674,839 and 5,714,576 to Hruby et al., *supra*);

(c) cyclic analogs of α -MSH using pseudoisosteric replacement of Met⁴ and Gly¹⁰ with Cys amino acids Ac-[Cys⁴, Cys¹⁰]- α -MSH_{1,13}NH₂ (See U.S. Patent Nos. 5,674,839 and 5,714,576 to Hruby et al., *supra*);

(d) linear analogs of the formula: R₁-W-X-Y-Z-R₂ (See U.S. Patent No. 4,918,055 to Hruby et al., *supra*); wherein

R₁ is selected from the group consisting of Ac-Gly-, Ac-Met-Glu-, Ac-Nle-Glu- and Ac-Tyr-Glu-;

W is selected from the group consisting of -His- and -D-His-;

X is selected from the group consisting of -Phe-, -D-Phe-, -Tyr-, -D-Tyr-, (-pNO₂)D-Phe⁷-;

Y is selected from the group consisting of -Arg- and -D-Arg-;

Z is selected from the group consisting of -Trp- and -D-Trp-; and,

R₂ is selected from the group consisting of -NH₂, -Gly-NH₂, and -Gly-Lys-NH₂;

(e) linear α -MSH analogs having the formula:

Ac-Ser-Tyr-Ser-M-Glu-His-D-Phe-Arg-Trp-Gly-Lys-Pro-Val-NH₂ (SEQ ID NO:4), wherein M is selected from the group consisting of Met, Nle, and Cys (See U.S. Patent No. 4,918,055 to Hruby et al., *supra*);

(f) linear α -MSH analogs selected from the group consisting of:

[Nle⁴, D-Phe⁷]- α -MSH;

[Nle⁴, D-Phe⁷]- α -MSH_{4,10};

[Nle⁴, D-Phe⁷]- α -MSH_{4,11};

[Nle⁴, D-Phe⁷, D-Trp⁹]- α -MSH_{4,11}; and,

[Nle⁴, D-Phe⁷]- α -MSH_{4,9} (See U.S. Patent No. 4,918,055 to Hruby et al., *supra*); and,

(g) cyclic bridged analogs of α -MSH having the general structure (See U.S. Patent No. 5,683,981 to Hadley et al., *supra*)

wherein AA⁵ may be either a L- or D- amino acid having an omega amino or
 5 carboxyl group in the side chain, e.g., α, γ -diaminopropionic acid, α, γ -diaminobutyric
 acid, Orn, Lys, α, β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or
 Asp;

wherein AA¹⁰ may be diaminopropionic acid, α, γ -diaminobutyric acid, Orn, Lys,
 α, β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

10 wherein R₁ is the designation α -MSH₁₋₁₃NH₂, α -MSH₁₋₁₂NH₂, α -MSH₁₋₁₁NH₂, α -
 MSH₄₋₁₃NH₂, or α -MSH₄₋₁₀NH₂;

wherein AA¹¹ may be L- or D- amino acid having an omega-amino or carboxyl
 group in the side chain, e.g., α, β -diaminopropionic acid; α, γ -diaminobutyric acid, Orn,
 Lys, α -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

15 wherein R₂ is the designation α -MSH₁₋₁₃NH₂, α -MSH₁₋₁₂NH₂, α -MSH₁₋₁₁NH₂, α -
 MSH₄₋₁₃NH₂, or α -MSH₄₋₁₀NH₂; and,

wherein Xxx may be from 1 to 5 α -amino acid residues each of which may be of
 L- or D- configuration, or a linear or branched chain spacer.

MSH analogs which may be particularly useful as α -MSH antagonists (See U.S.,
 20 Patent No. 4,649,191 to Hruby et al., *supra*) include, but are not limited to:

(a) cyclic analogs having the general formula (See U.S. Patent No. 5,731,408 to
 Hadley et al., *supra*) :

48

(SEQ ID NO:6); and,

(b) cyclic analogs having the general formula (See U.S. Patent No. 4,649,191 to Hruby et al., *supra*):

5

(1)

wherein R^1 is a substituted or unsubstituted aromatic radical;

R^2 is hydrogen or a methyl group;

10 R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

R^4 is glutamic acid, alanine, -amino butyric acid, valine, leucine or isoleucine;

R^5 is histidine, glutamic acid, alanine, valine, leucine or isoleucine;

R^6 and R^7 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

15 R^8 and R^9 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

X and Y are sulfur, methylene, SO or SO_2 ;

Z is $-\text{NH}_2$.

and,

n is an integer greater than or equal to 2;

(2)

wherein R¹ is phenyl, indole, p-hydroxyphenyl, p-aminophenyl, imidazole, 1-naphthyl adamantyl or alkylphenyl, 2-naphthyl;

R² is hydrogen or a methyl group;

R³ is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂;

and,

n is an integer greater than or equal to 2; and wherein the cyclized portion of the compound is conformationally restricted in a manner which is compatible with the reactivity of the compound with receptors of the central nervous system.

In one embodiment of the present invention, POMC homologues and mimetics have increased or decreased stability and/or increased or decreased biological activity compared to an unmodified POMC peptide (i.e., a naturally occurring or prototype POMC peptide). As used herein, the biological activity or biological action of a protein (e.g., a peptide) refers to any function(s) exhibited or performed by a naturally occurring form of the protein as measured or observed *in vivo* (i.e., in the natural physiological environment of the protein in the organism) or *in vitro* (i.e., under laboratory conditions, in tissue culture or cell free systems, for example). For example, a biological activity of

a protein can include, but is not limited to, hormone activity, protein binding activity, receptor binding activity, calcium binding activity, protein translocation, or DNA binding activity. Modifications of a protein, such as in a homologue or mimetic, which result in a decrease in protein expression or a decrease in the activity of the protein, can be referred to as inactivation (complete or partial), down-regulation, or decreased action of a protein. Similarly, modifications which result in an increase in protein expression or an increase in the activity of the protein, can be referred to as amplification, overproduction, activation, enhancement, up-regulation or increased action of a protein.

In accordance with the present invention, increased stability refers to the property of a POMC homologue or mimetic to have a longer half-life (i.e., have greater stability under physiological conditions, such as in serum), by being more resistant, for example, to proteolytic degradation compared to proteins comprising unmodified POMC peptides, to higher or lower temperature, to more acidic or basic pH, to higher or lower salt concentrations, to oxidation and/or reduction, to deamidation, and to other forms of chemical or biological degradation. Similarly, decreased stability refers to the property of a mimetic to be less resistant, for example, to such conditions.

According to the present invention, an isolated or biologically pure protein, including peptides and analogs thereof, is a protein that has been removed from its natural milieu. As such, "isolated" and "biologically pure" do not necessarily reflect the extent to which the protein has been purified. An isolated protein of the present invention can be obtained from its natural source, can be produced using recombinant DNA technology or can be produced by chemical synthesis. Such methods are described in detail below. It is to be noted that the term "a" or "an" entity refers to one or more of that entity; for example, a compound refers to one or more compounds or at least one compound. As such, the terms "a" (or "an"), "one or more" and "at least one" can be used interchangeably herein. It is also to be noted that the terms "comprising", "including", and "having" can be used interchangeably. Furthermore, a compound "selected from the group consisting of" refers to one or more of the compounds in the list that follows, including mixtures (i.e., combinations) of two or more of the compounds.

It will be particularly appreciated by one of skill in the art that by recognizing the benefits of using POMC peptides to regulate body weight in animals, compounds having

similar structural characteristics as the POMC peptides of the present invention (e.g., homologues, peptide mimetics and/or non-peptide mimetics) will also be apparent and are intended to be within the scope of the present invention. In other words, one of ordinary skill in the art, without undue experimentation, once they appreciate the role of POMC peptides, and particularly MSH, in the regulation of body weight, are able to isolate and/or synthesize various related compounds and mimetics having the desired, and preferably, improved therapeutic effect as achieved using the particular embodiments of the compounds described herein.

Another POMC compound useful in the method of the present invention includes a fusion protein that includes at least one POMC peptide (or a homologue or peptide mimetic thereof) attached to one or more fusion segments. Suitable fusion segments for use with the present invention include, but are not limited to, segments that can: enhance a protein's stability; act as an enhancer or inhibitor of the biological activity of a POMC peptide; and/or assist with the purification of a POMC peptide (e.g., by affinity chromatography). A suitable fusion segment can be a domain of any size that has the desired function (e.g., imparts increased stability, imparts increased biological activity to a protein, and/or simplifies purification of a protein). Fusion segments can be joined to amino and/or carboxyl termini of the POMC peptide and can also be susceptible to cleavage in order to facilitate recovery of an isolated protein comprising a POMC peptide. Fusion proteins are preferably produced by culturing a recombinant cell transformed with a fusion nucleic acid molecule that encodes a protein including the fusion segment attached to either the carboxyl and/or amino terminal end of a protein comprising a POMC peptide. Preferred fusion segments include a metal binding domain (e.g., a poly-histidine segment); an immunoglobulin binding domain (e.g., Protein A; Protein G; T cell, B cell, or Fc receptor; or complement protein antibody-binding domains); a sugar binding domain (e.g., a maltose binding domain); and/or a "tag" domain (e.g., at least a portion of β -galactosidase, a strep tag peptide, other domains that can be purified using compounds that bind to the domain, such as monoclonal antibodies).

The fusion protein can be used directly in the method of the present invention, or the desired peptide can be isolated for use in the method of the present invention by enzymatic or chemical cleavage. A variety of peptidases (e.g. trypsin) which cleave a

polypeptide at specific sites or digest the peptides from the amino or carboxy termini (e.g. diaminopeptidase) of the peptide chain are known. Furthermore, particular chemicals (e.g. cyanogen bromide) will cleave a polypeptide chain at specific sites. The skilled artisan will appreciate the modifications necessary to the amino acid sequence (and synthetic or
5 semi-synthetic coding sequence if recombinant means are employed) to incorporate site-specific internal cleavage sites. See e.g., P. Carter, "Site Specific Proteolysis of Fusion Proteins", Ch. 13 in Protein Purification: from Molecular Mechanisms to Large Scale Processes, American Chemical Society, Washington, D.C. (1990).

10 In one embodiment of the present invention, a POMC compound suitable for use in the method of the present invention includes an isolated nucleic acid molecule encoding a POMC peptide, peptide analog thereof, or fusion protein comprising such a peptide, each of which has been described in detail above. Preferably, such an isolated nucleic acid molecule is in the form of a recombinant nucleic acid molecule or as "naked DNA", both of which are described in detail below.

15 The compounds useful for carrying out the present invention may be produced by any method suitable for the production of peptides and/or non-peptide mimetics, and particularly, for POMC peptides or non-peptide mimetics. For example, such methods include well known chemical procedures, such as solution or solid-phase peptide synthesis, or semi-synthesis in solution beginning with protein fragments coupled through
20 conventional solution methods. Such methods are well known in the art and may be found in general texts and articles in the area such as: Merrifield, 1997, *Methods Enzymol.* 289:3-13; Wade et al., 1993, *Australas Biotechnol.* 3(6):332-336; Wong et al., 1991, *Experientia* 47(11-12):1123-1129; Carey et al., 1991, *Ciba Found Symp.* 158:187-203; Plaue et al., 1990, *Biologicals* 18(3):147-157; Bodanszky, 1985, *Int. J. Pept. Protein Res.*
25 25(5):449-474; or H. Dugas and C. Penney, *BIOORGANIC CHEMISTRY*, (1981) at pages 54-92, all of which are incorporated herein by reference in their entirety. For example, peptides may be synthesized by solid-phase methodology utilizing a commercially available peptide synthesizer and synthesis cycles supplied by the manufacturer. One skilled in the art recognizes that the solid phase synthesis could also
30 be accomplished using the Fmoc strategy and a TFA/scavenger cleavage mixture. Methods for synthesizing MSH analogs, for example, are described in detail in U.S. Patent

No. 4,649,191 to Hruby, *supra*, U.S. Patent No. 4,918,055 to Hruby et al., *supra*, U.S. Patent No. 5,674,839 to Hruby et al., *supra*, U.S. Patent No. 5,683,981 to Hadley et al., *supra*, U.S. Patent No. 5,714,576 to Hruby et al., *supra*, and U.S. Patent No. 5,731,408 to Hruby et al., *supra*, all of which are incorporated herein by reference in their entirety.

5 If larger quantities of a POMC peptide are desired, the peptide (or a peptide analog thereof) can be produced using recombinant DNA technology, although for proteins of this small size (i.e., peptides), peptide synthesis is generally preferred. A peptide can be produced recombinantly by culturing a cell capable of expressing the peptide (i.e., by expressing a recombinant nucleic acid molecule encoding the peptide)
10 under conditions effective to produce the peptide, and recovering the peptide. Such techniques are well known in the art and are described, for example, in Sambrook et al., 1988, *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Press, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York or *Current Protocols in Molecular Biology* (1989) and supplements.

15 An isolated nucleic acid molecule encoding a POMC peptide or peptide analog thereof (i.e., a homologue or peptide mimetic) can be isolated from its natural source or produced using recombinant DNA technology (e.g., polymerase chain reaction (PCR) amplification, cloning) or chemical synthesis. Methods for producing synthetic nucleic acid molecules are well known in the art. For example, since the POMC peptides are
20 relatively small peptides, the DNA sequence coding for the desired protein may be generated using conventional, commercially available DNA synthesizing apparatus. Alternatively, DNA encoding the desired protein may also be created by using polymerase chain reaction (PCR) techniques or other cloning techniques from genomic DNA of many species. The template also can be a cDNA library or mRNA isolated from central nervous
25 system or pituitary tissue. Such methodologies are well known in the art (Sambrook et al., *supra*).

 Isolated nucleic acid molecules encoding POMC peptides or peptide analogs thereof can be modified from the nucleic acid molecule encoding the prototype peptide by nucleotide insertions, deletions, and substitutions (e.g., nucleic acid homologues) in a
30 manner such that the modifications do not substantially interfere with the nucleic acid molecule's ability to encode a POMC peptide, homologue or mimetic that is useful in the

present invention. For example, it may be desirable in some applications to modify the coding sequence of the desired protein so as to incorporate a convenient protease sensitive cleavage site, e.g., between the signal peptide and the structural protein facilitating the controlled excision of the signal peptide from the fusion protein construct.

5 An isolated nucleic acid molecule encoding a POMC peptide can include degeneracies. As used herein, nucleotide degeneracies refers to the phenomenon that one amino acid can be encoded by different nucleotide codons. Thus, the nucleic acid sequence of a nucleic acid molecule that encodes a POMC peptide of the present invention can vary due to degeneracies.

10 One embodiment of the present invention includes a recombinant nucleic acid molecule, which includes at least one isolated nucleic acid molecule encoding a peptide as described above, inserted into any suitable vector capable of delivering the nucleic acid molecule into a host cell to form a recombinant cell and/or capable of allowing expression of the protein encoded by the nucleic acid molecule. Such a vector typically contains
15 heterologous nucleic acid sequences, that is, nucleic acid sequences that are not naturally found adjacent to nucleic acid molecules of the present invention. The vector can be either RNA or DNA, either prokaryotic or eukaryotic, and typically is a virus or a plasmid. Recombinant vectors can be used in the cloning, sequencing, and/or otherwise manipulating of POMC peptide-encoding nucleic acid molecules of the present invention.

20 In accordance with the present invention, an isolated nucleic acid molecule is a nucleic acid molecule that has been removed from its natural milieu (i.e., that has been subject to human manipulation) and can include DNA, RNA, or derivatives of either DNA or RNA. As such, "isolated" does not reflect the extent to which the nucleic acid molecule has been purified. As used herein, the phrase "recombinant molecule" primarily
25 refers to a nucleic acid molecule or nucleic acid sequence operatively linked to a transcription control sequence, but can be used interchangeably with the phrase "nucleic acid molecule". It will be appreciated that a double stranded DNA which encodes a given amino acid sequence comprises a single strand DNA and a complementary strand having a sequence that is a complement to the single strand DNA. As such, nucleic acid
30 molecules which encode a POMC peptide of the present invention can be either double-stranded or single-stranded, and include those nucleic acid molecules that encode any of

the POMC peptides (including homologues and peptide mimetics) as described herein and as are known in the art.

In order to express the desired peptide, the isolated nucleic acid molecule is operatively linked to one or more transcription control sequences. According to the present invention, the phrase "operatively linked" refers to linking a nucleic acid molecule to a transcription control sequence in a manner such that the molecule is able to be expressed when transfected (i.e., transformed, transduced or transfected) into a host cell. Transcription control sequences are sequences which control the initiation, elongation, and termination of transcription. Particularly important transcription control sequences are those which control transcription initiation, such as promoter, enhancer, operator and repressor sequences. Suitable transcription control sequences include any transcription control sequence that can function in at least one of the recombinant cells useful for expressing a POMC peptide of the present invention. A variety of such transcription control sequences are known to those skilled in the art. Preferred transcription control sequences include those which function in bacterial, yeast, insect or mammalian cells.

Recombinant molecules can also contain additional regulatory sequences, such as translation regulatory sequences, origins of replication, and other regulatory sequences that are compatible with a recombinant cell (i.e., a cell that has been transfected with the recombinant nucleic acid molecule). In one embodiment, a recombinant molecule of the present invention also contains secretory signals (i.e., signal segment nucleic acid sequences) to enable an expressed POMC peptide to be secreted from a cell that produces the protein. Suitable signal segments include a signal segment that is naturally associated with a POMC peptide according to the present invention or any heterologous signal segment capable of directing the secretion of a POMC peptide as is desired according to the present invention. In another embodiment, a recombinant molecule of the present invention comprises a leader sequence to enable an expressed POMC peptide to be delivered to and inserted into the membrane of a host cell. Suitable leader sequences include a leader sequence that is naturally associated with a POMC peptide of the present invention, or any heterologous leader sequence capable of directing the delivery and insertion of a POMC peptide to the membrane of a cell.

Another type of recombinant vector, referred to herein as a recombinant virus, includes a recombinant nucleic acid molecule encoding a POMC peptide or analog thereof that is packaged in a viral coat and that can be expressed in a cell after delivery of the virus to the cell. A number of recombinant virus particles can be used, including, but not limited to, those based on alphaviruses, poxviruses, adenoviruses, herpesviruses, and retroviruses.

Another type of recombinant nucleic acid molecule encompassed by the present invention is a naked nucleic acid molecule, which preferably includes a recombinant molecule as described above that preferably is replication, or otherwise amplification, competent. A naked nucleic acid reagent of the present invention can comprise one or more nucleic acid molecule of the present invention in the form of, for example, a dicistronic recombinant molecule. Preferred naked nucleic acid molecules include at least a portion of a viral genome (i.e., a viral vector).

One or more recombinant molecules of the present invention can be used to produce an encoded product (i.e., a POMC peptide or analog or fusion protein thereof) of the present invention. In one embodiment, an encoded product is produced by expressing a nucleic acid molecule as described herein under conditions effective to produce the protein. A preferred method to produce an encoded protein is by transfecting a host cell with one or more recombinant molecules to form a recombinant cell. Suitable host cells to transfect include any bacterial, yeast, insect or mammalian cell that can be transfected. Host cells can be either untransfected cells or cells that are already transformed with at least one nucleic acid molecule.

In accordance with the present invention, recombinant cells can be used to produce POMC peptides (including analogs and fusion proteins thereof) by culturing such cells under conditions effective to produce such a protein, and to recover the protein. Effective conditions to produce a protein include, but are not limited to, appropriate media, bioreactor, temperature, pH and oxygen conditions that permit protein production. An appropriate medium refers to any medium in which a cell of the present invention, when cultured, is capable of producing POMC peptides. An effective medium is typically an aqueous medium comprising assimilable carbohydrate, nitrogen and phosphate sources, as well as appropriate salts, minerals, metals and other nutrients, such as vitamins. The

medium may comprise complex nutrients or may be a defined minimal medium. Cells of the present invention can be cultured in conventional fermentation bioreactors, which include, but are not limited to, batch, fed-batch, cell recycle, and continuous fermentors. Culturing can also be conducted in shake flasks, test tubes, microtiter dishes, and petri
5 plates. Culturing is carried out at a temperature, pH and oxygen content appropriate for the recombinant cell. Such culturing conditions are well within the expertise of one of ordinary skill in the art.

Depending on the vector and host system used for production, resultant proteins may either remain within the recombinant cell; be secreted into the culture medium; be
10 secreted into a space between two cellular membranes, such as the periplasmic space in *E. coli*; or be retained on the outer surface of a cell or viral membrane. The phrase "recovering the protein" refers simply to collecting the whole culture medium containing the protein and need not imply additional steps of separation or purification. POMC peptides of the present invention can be purified using a variety of standard protein
15 purification techniques, such as, but not limited to, affinity chromatography, ion exchange chromatography, filtration, electrophoresis, hydrophobic interaction chromatography, gel filtration chromatography, reverse phase chromatography, chromatofocusing and differential solubilization.

In another embodiment of the present invention, a POMC peptide can be
20 expressed by a recombinant nucleic acid molecule or virus encoding the peptide at a desired site *in vivo*. In this embodiment, a recombinant nucleic acid molecule or virus encoding a POMC peptide, can be administered to an animal as a means of gene therapy. Such a method is particularly useful for animals which have obesity problems related to a POMC-peptide deficiency, although such a method can be used for any patient wherein
25 regulation of body weight is desired. The use of gene therapy vehicles has generally been described in the art (See for example, U.S. Patent No. 5,593,972, issued January 14, 1997, to Weiner et al.; U.S. Patent No. 5,580,859, issued December 3, 1996, to Felgner et al.; U.S. Patent No. 5,589,466, issued December 31, 1996, to Felgner et al.; U.S. Patent No. 5,641,662, issued June 24, 1997, to Debs et al. and U.S. Patent No.
30 5,676,954, issued October 14, 1997, to Brigham, all of which are incorporated herein by reference in their entirety). Such publications have disclosed gene therapy protocols

which include administration of nucleic acid molecules (e.g., DNA) encoding any of a variety of other proteins, which are administered to an animal by a variety of administration routes, and using a variety of delivery mechanisms. Preferred methods for delivery of nucleic acid molecules to a patient are discussed in more detail below.

5 While the present invention, in one embodiment, is directed to the use of POMC compounds alone, it can also be used in combination with other agents, and particularly other body weight regulating agents, including, but not limited to, leptin. Indeed, the present inventors provide evidence herein that the combination of leptin and MSH is has a synergistic effect in treatment of obesity. As used herein, the term "leptin" refers to the
10 protein produced from the obesity (*ob*) gene following transcription and deletion of introns, translation to a protein and processing to the mature protein with secretory signal peptide, removed, e.g., from the N-terminal valine-proline to the C-terminal cysteine of the mature protein. The amino acid sequences of the mouse obesity protein and human obesity protein are published in Zhang et al., *supra*. The amino acid sequence of the rat
15 obesity protein is published in Murakami et al., *Biochemical and Biophysical Research Comm* 209(3): 944-52 (1995), incorporated herein by reference in its entirety. Leptin and leptin mimetics are described in detail in U.S. Patent No. 5,756,461, which is incorporated herein by reference in its entirety. In one embodiment of the invention, leptin is
20 administered in combination with apolipoprotein J (ApoJ). U.S. Patent No. 5,830,450 to Lallone, incorporated herein by reference in its entirety, describes the use of ApoJ bound to leptin in a composition for the diagnosis and treatment of obesity.

 In the embodiment wherein an increase in body weight is desired, while the POMC antagonist compounds can be used alone, they can also be used in combination with other agents, and particularly other body weight regulating agents, including, but not limited to,
25 anabolic steroids, growth hormone, erythropoietin, cytokines, and anti-cytokine agents.

 The method of the present invention is useful for treating any animal for the purposes of regulating body weight, including decreasing body weight and/or reducing the rate of weight gain, or increasing body weight and/or decreasing the rate of weight loss. In one embodiment, the method of the present invention is particularly useful for treating
30 obesity. As used herein, the terms "obese" and "obesity" are used to refer to a condition in which an animal (typically human) has a body mass index (BMI) of greater than 27

kilograms per square meter. The phrase, "to treat obesity" in a patient refers to reducing, ameliorating or preventing obesity in a patient that suffers from obesity or is at risk of becoming obese. Therefore, in one embodiment of the present invention, "to treat" a disorder such as obesity can also mean "to prevent" the disorder in a patient. Preferably, the disorder (e.g., obesity), or the potential for developing the disorder, is reduced, optimally, to an extent that the patient no longer suffers from or does not develop the disorder (e.g., excessive accumulation of fat stores in adipose tissue), or the discomfort and/or altered functions and detrimental conditions associated with such disorder. More particularly, "to control" or "to regulate" body weight, or specifically "to treat obesity", includes the administration of POMC compounds as disclosed herein to prevent the onset of the symptoms or complications of undesired body weight, to alleviate the symptoms or complications, or to eliminate the disorder. Treating obese patients, for example, may include but is not limited to, lowering body weight and/or decreasing the rate of weight gain. Individuals having a BMI equal to or less than 27 kilograms per square meter, while not considered to be obese according to the present invention, can also be treated using the method of the present invention to reduce body weight, for example, for cosmetic purposes, athletic training purposes, or for health-associated purposes. The present invention is also useful for treating individuals (e.g., patients) with a percent body fat greater than 20%, and preferably, greater than about 25%, and more preferably, greater than about 30%, and even more preferably, greater than about 35%, 40%, and 45%, in increasing preference. It is to be noted that certain individuals, such as certain athletes, can actually have a BMI greater than 27 kilograms per square meter, while having a relatively low or healthy percent body fat, and therefore, one of skill in the art will appreciate that such individuals may not actually be considered to be obese. Additionally, the present invention is useful for treating patients having undesirable low body weight by administration of POMC antagonists. The method of the present invention relates to protocols for modifying the action of the central and/or peripheral, melanocortinergeric and/or leptinergeric pathways of energy homeostasis, and particularly, the peripheral pathways.

The methods disclosed herein can also be used in conjunction with other methods related to the treatment of excess body weight or related conditions, including, but not

limited to, coadministration of another body weight regulating compound (e.g., leptin), exercise, diet, or liposuction (for example, post-operative or post-dietetic administration of a therapeutic composition of the present invention could be used to reduce the reoccurrence of weight gain, to generally reduce adipose tissue in areas of the patient's body which were not treated or to attempt to reset the metabolic "set point" for weight regulation).

In another embodiment, the method of the present invention is useful for treating any animal for the purposes of increasing body weight and/or mass and/or decreasing the rate of weight and/or mass loss. In particular, this embodiment of the method of the present invention is useful for treating any animal that has a wasting syndrome or other undesirable loss in body weight and/or body mass including, but not limited to, wasting disease, cachexia or sarcopenia. The phrase, "to treat" a condition such as cachexia in a patient refers to reducing, ameliorating or preventing the condition in a patient that suffers from the condition or is at risk of acquiring the condition. Therefore, in one embodiment of the present invention, "to treat" a disorder can also mean "to prevent" the disorder in a patient. Preferably, the condition, or the potential for developing the condition, is reduced, optimally, to an extent that the patient no longer suffers from the condition or begins to accumulate fat stores in adipose tissue and/or body cell mass, or to decrease the discomfort and/or altered functions and detrimental conditions associated with the loss of fat stores and body cell mass. More particularly, "to treat" a condition associated with undesired weight and/or mass loss includes the administration of POMC antagonist compounds as disclosed herein to prevent the onset of the symptoms or complications of such a condition, to alleviate the symptoms or complications, or to eliminate the condition. Treating patients suffering from undesired weight and/or mass loss, such as cachexia, for example, may include but is not limited to, increasing body weight and/or mass and/or decreasing the rate of weight and/or mass gain. The method of the present invention relates to protocols for modifying the action of the central and/or peripheral, melanocortinerbic and/or leptinerbic pathways of energy homeostasis, and particularly, the peripheral pathways.

The methods disclosed herein can also be used in conjunction with other methods related to the treatment of undesired body weight and/or mass loss or related conditions,

including, but not limited to, coadministration of another body weight regulating compound (e.g., anabolic steroids, growth hormone, erythropoietin, cytokines, and anti-cytokine agents) and diet.

In a preferred embodiment, the present invention provides a method for treating
5 patients having low MSH and/or leptin levels, although patients with high endogenous
leptin and or MSH levels may also benefit from the present methods. Methods for
assaying serum and plasma leptin and MSH levels may be accomplished using standard
antibody-based methodologies. Leptin assay kits are also commercially available from
10 Linco Research, Inc. (14 Research Park Dr., St Louis, Mo. 63304). MSH assay
antibodies are commercially available from ICN BioMedicals, Inc. and MSH assay kits are
commercially available from IBL (Hamburg, Germany). Serum MSH levels typically
average about 0.15 ng/ml in humans and are about 10 fold higher in other animals, such
as mice (average 2 ng/ml). Treating patients having MSH levels between 0 and 10 ng/ml
is preferred. More highly preferred is to treat patients having MSH levels between 0 and
15 1 ng/ml. Most preferred is to treat patients having MSH levels between 0 and 0.1 ng/ml.
More preferred is to treat patients having leptin levels between 0 and 50 ng/ml. More
highly preferred is to treat patients having leptin levels between 0 and 30 ng/ml. Most
preferred is to treat patients having leptin levels between 0 and 15 ng/ml. Preferably, a
patient to be treated has a mass to mass ratio of serum MSH to serum leptin of greater
20 than 1:100 prior to the step of administration. In one embodiment of the present
invention, the method includes administering to a patient in whom body weight regulation
is desired a composition comprising both a POMC compound according to the present
invention and leptin, wherein the ratio of MSH to leptin to be administered is effective to
regulate body weight in the patient. Preferably, the ratio of MSH to leptin in the
25 composition is about 1:100, and more preferably, about 1:25 and even more preferably,
about 1:10.

In the practice of the present invention, it is useful, although not essential, to
prepare therapeutic compositions (i.e., pharmaceutical formulations) comprising an
effective amount of at least one POMC compound according to the present invention,
30 either alone or in combination with one or more other body weight regulating formulations
or compounds as previously described herein (i.e., leptin). Such compositions, preferably

in the form of a pharmaceutically acceptable salt and/or complexed with another suitable pharmaceutically acceptable carrier (described below), can be formulated for any route of administration, including, but not limited to, parenteral administration and transdermal administration. In one embodiment, the therapeutic composition comprises an agent
5 which further minimizes delivery of the POMC compound to the central nervous system, such an agent including, but not limited to an antagonist of MC4-R, an agent that inhibits the binding of a POMC peptide to MC4-R (e.g., an antibody against MC4-R or a competitive inhibitor for MC4-R binding), and/or an agent that inhibits the POMC compound from entering the central nervous system (e.g., by preventing the compound
10 from crossing the blood-brain barrier).

According to the present invention, to "minimize" delivery of a POMC compound to the central nervous system or to minimize effects of the methods of the present invention on the central nervous system, means that biological activities which result from the action of a POMC compound on a receptor and/or cell in the central nervous system
15 are intentionally (preferentially) reduced, inhibited, blocked, decreased, mitigated, or avoided as compared to the biological activities which result from the action of the POMC compound on the peripheral receptors and cells. Various means by which such minimization is accomplished are discussed in detail herein, and include, but are not limited to, peripheral routes of administration (no direct administration to the central
20 nervous system), selection of doses which are insufficient to have a significant effect on central receptor biological activity and/or appetite in the animal, selection of POMC compounds which preferentially bind to and/or activate peripheral receptors as compared to central receptors.

In a preferred embodiment of the present invention, a therapeutic composition
25 comprising a POMC compound, alone or in combination with one or more additional body weight regulating compounds, is formulated to be administered in a manner which extends the time the composition remains in the bloodstream of an animal. As such, a therapeutic composition of the present invention typically includes a pharmaceutically acceptable carrier, and preferably, one which is capable of delivering the composition of
30 the present invention to the peripheral circulation of the animal, and in some cases, is capable of prolonging the action of the composition in the bloodstream of the animal.

For example, therapeutic compositions (i.e., formulations) of the present invention can be formulated in an excipient that the animal to be treated can tolerate. In one embodiment, such an excipient is suitable for use in a composition which is to be administered for delivery to the peripheral circulation. Examples of such excipients
5 include water, saline, phosphate buffered solutions, Ringer's solution, dextrose solution, Hank's solution, polyethylene glycol-containing physiologically balanced salt solutions, and other aqueous, physiologically balanced, salt solutions. Nonaqueous vehicles, such as fixed oils, sesame oil, ethyl oleate, or triglycerides may also be used. Other useful formulations include suspensions containing viscosity enhancing agents, such as sodium
10 carboxymethylcellulose, sorbitol, or dextran. Excipients can also contain minor amounts of additives, such as substances that enhance isotonicity and chemical stability or buffers. Examples of buffers include phosphate buffer, bicarbonate buffer and Tris buffer, while examples of preservatives include thimerosal, — or o-cresol, formalin and benzyl alcohol. Standard formulations can either be liquid injectables or solids which can be taken up in
15 a suitable liquid as a suspension or solution for injection. Thus, in a non-liquid formulation, the excipient can comprise dextrose, human serum albumin, preservatives, etc., to which sterile water or saline can be added prior to administration.

The compositions comprising one or more desired compounds typically contain from about 0.1% to 90% by weight of the active compound, preferably in a soluble form,
20 and more preferably, from about 0.1% to about 50%, and more preferably from about 0.1% to about 25%, and even more preferably, from about 0.1% to about 10%, and even more preferably, from about 0.1% to 1.0%.

In one embodiment of the present invention, a pharmaceutically acceptable carrier can include additional compounds that increase the half-life of a therapeutic composition
25 in the treated animal. Suitable carriers include, but are not limited to, polymeric controlled release vehicles, biodegradable implants, liposomes, bacteria, viruses, other cells, oils, esters, and glycols.

In one embodiment of the present invention, a therapeutic composition can include a controlled release composition that is capable of slowly releasing the formulation into
30 a patient. As used herein, a controlled release composition comprises a POMC compound as described herein in a controlled release vehicle. Suitable controlled release vehicles

include, but are not limited to, biocompatible polymers, polymeric matrices, capsules, microcapsules, microparticles, bolus preparations, osmotic pumps, diffusion devices, liposomes, lipospheres, and transdermal delivery systems. Other controlled release compositions of the present invention include liquids that, upon administration to an animal, form a solid or a gel *in situ*. Preferred controlled release compositions are biodegradable (i.e., bioerodible).

One embodiment of the present invention relates to a transdermal patch for delivering the therapeutic composition of the present invention. Such a patch can include additional compounds for enhancing the delivery (i.e., transfer) of components across the epidermal surface of the skin and into the peripheral circulation (e.g., DMSO).

A preferred controlled release composition of the present invention is capable of releasing a formulation of the present invention into the blood of an animal at a constant rate sufficient to maintain therapeutic levels of the formulation to control body weight over a period of time ranging from days to months based on toxicity parameters. A controlled release formulation of the present invention is capable of effecting control over body weight for preferably at least about 6 hours, more preferably at least about 24 hours, and even more preferably for at least about 7 days.

According to the present invention, an effective administration protocol (i.e., administering a POMC compound or a therapeutic composition comprising such a compound in an effective manner) comprises suitable dose parameters and modes of administration that result in regulation of body weight in the animal when administered one or more times over a suitable time period. In one embodiment, an effective administration protocol results in a measurable regulation of body weight and/or body mass of an animal within at least about 2 weeks after the first administration of POMC compound, and more preferably, within at least one week, and more preferably, within at least 3 days, and even more preferably, within at least 24 hours of the first administration of a POMC compound.

Effective dose parameters can be determined using methods standard in the art for a particular animal and condition. Such methods include, for example, determination of survival rates, side effects (i.e., toxicity) and other health factors associated with, or in addition to the amount of body weight loss or gain desired in the animal. In particular,

the effectiveness of dose parameters of a therapeutic composition of the present invention when used to control body weight can be determined by assessing response rates. Such response rates refer to the percentage of treated patients in a population of patients that respond with either partial or complete loss of excess weight, or a reduction in the rate of weight gain, or alternatively, to a partial or complete gain of lost weight or a reduction in the rate of weight loss, as compared to a previous, healthy or normal weight and/or mass for the patient prior to the onset of the disorder or as compared to a population normalized healthy or normal weight and/or mass, to a level which is considered by those of skill in the art to be sufficient to address the needs of the particular patient and/or not present health risks to the patient. Response can be determined by, for example, measuring weight loss over time and/or measuring changes in levels of hormones and other biological indicators of obesity and metabolic control in the animal, for example, leptin.

In one embodiment, a response can be evaluated by determining whether the animal's leptin and/or MSH levels in serum are more similar to a "normal population control" than prior to the treatment. As discussed elsewhere herein, an average human serum MSH level is about 0.15 ng/ml, with lower levels being indicative of a metabolic dysfunction which may lead to weight gain. An average serum leptin level for humans is about 10 ng/ml, with higher levels being indicative of a metabolic dysfunction and/or obesity. In a patient who may have a metabolic dysfunction, the levels of MSH may be lower than normal and/or the levels of leptin may be higher than normal, resulting in a change in the ratio of MSH to leptin. Therefore, as another means of comparison, a "normal human" ratio of MSH to leptin is typically about 1:100 (mass to mass), whereas variations in this ratio may indicate a metabolic dysfunction (e.g., an increase in the ratio of MSH to leptin to 1:500 may indicate a propensity for weight gain). In one embodiment of the present invention, a POMC peptide is administered to an animal in an amount effective to restore the ratio of MSH to leptin to about normal levels (e.g., nearer to MSH:leptin = 1:100).

Modes of administration of a therapeutic composition of the present invention include any method of administration which results in delivery of the composition to the peripheral circulation of the animal. According to the present invention, the phrase

"peripheral administration" or "peripheral delivery" refers to any route of administration which delivers a composition of the present invention to the peripheral circulation, cells and/or tissues of an animal. Peripheral administration is distinguished from routes of administration which are specifically intended to deliver a composition directly to the central nervous system (e.g., by direct injection into the brain or other central nervous system tissues), although it is to be understood that a peripheral route of administration may result in some composition reaching the cells and tissues of the central nervous system. Such modes of administration can include, but are not limited to, oral, nasal, topical, transdermal, rectal, and parenteral routes, as well as direct injection into a tissue and delivery by a catheter. Parenteral routes can include, but are not limited to subcutaneous, intradermal, intravenous, intraperitoneal and intramuscular routes. In one embodiment, the route of administration is by topical or transdermal administration, such as by a lotion, cream, a patch, an injection, an implanted device (e.g., similar to Norplant), or other controlled release carrier. Preferred routes of administration include transdermal delivery and delivery via an implanted device or other controlled release carrier. Particularly preferred routes of administration include any route which directly delivers the composition to the systemic circulation (e.g., by injection), including any parenteral route. It is noted that one of skill in the art will be able to use the guidance provided herein regarding route of administration, pharmaceutical carriers or excipients, and dosage, to select an administration protocol which delivers the composition of the present invention to the peripheral circulation, as opposed to, for example, merely delivering the composition to the dermal tissue as has been previously described for MSH for the use in the treatment of dermal conditions (e.g., vitiligo or dermatitis). Although topical and transdermal delivery of MSH and analogs thereof has been described prior to the present invention (e.g., U.S. Patent No. 4,874,744 to Nordlund or U.S. Patent No. 4,649,191 to Hruby et al.), such methods were directed to the treatment of conditions at the dermis, and therefore these methods taught dosage protocols, carriers and administration methods which were suitable for delivering MSH to the dermis for action at the skin, but failed to describe doses, carriers and/or administration methods that are suitable for delivery of MSH to the peripheral circulation, which is where the method of the present invention acts. For example, these methods typically suggested concentration ranges for MSH (e.g.,

10^{-10} , 10^{-11}) which are *well below* the level which would be expected to provide a significant effect in the method of the present invention.

In the embodiment where the POMC compound is to be delivered to a patient in the form of a nucleic acid molecule encoding a POMC peptide or peptide analog thereof, the nucleic acid molecules can be delivered to a patient by a variety of methods including, but not limited to, (a) administering a naked (i.e., not packaged in a viral coat or cellular membrane) nucleic acid molecule (e.g., as naked DNA or RNA molecules, such as is taught, for example in Wolff et al., 1990, Science 247, 1465-1468); (b) administering a nucleic acid molecule packaged as a recombinant virus, in a liposome delivery vehicle, or in a recombinant cell (i.e., the nucleic acid molecule is delivered by a viral or cellular vehicle); or (c) administering a recombinant nucleic acid molecule encapsulated within a liposome delivery vehicle.

Naked nucleic acid molecules can be administered in a variety of ways, with intramuscular, subcutaneous, intradermal, transdermal, intranasal and oral routes of administration being preferred. A preferred single dose of a naked nucleic acid molecule ranges from about 1 nanogram (ng) to about 100 μ g, depending on the route of administration and/or method of delivery, as can be determined by those skilled in the art. Suitable delivery methods include, for example, by injection, as drops, aerosolized and/or topically. Naked DNA can be contained in an aqueous excipient (e.g., phosphate buffered saline) alone or a carrier (e.g., lipid-based vehicles).

Suitable liposomes for use with the present invention include any liposome. Preferred liposomes of the present invention include those liposomes commonly used in, for example, gene delivery or protein delivery methods known to those of skill in the art, including, but not limited to, multilamellar vesicle (MLV) lipids, extruded lipids and small unilamellar vesicle (SUV) lipids.

Complexing a liposome with a nucleic acid molecule encoding a POMC peptide compound of the present invention can be achieved using methods standard in the art (See, for example, U.S. Patent No. 5,593,972, issued January 14, 1997, to Weiner et al.; U.S. Patent No. 5,580,859, issued December 3, 1996, to Felgner et al.; U.S. Patent No. 5,589,466, issued December 31, 1996, to Felgner et al.; U.S. Patent No. 5,641,662, issued June 24, 1997, to Debs et al. and U.S. Patent No. 5,676,954, issued October 14, 1997,

to Brigham, all of which are incorporated herein by reference in their entirety.) A suitable concentration of a nucleic acid molecule encoding a POMC peptide compound of the present invention to add to a liposome includes a concentration effective for delivering a sufficient amount of nucleic acid molecule into a mammal such that the POMC peptide
5 compound can be expressed and have the desired biological effect. Preferably, the ratio of nucleic acids to lipids (μg nucleic acid:nmol lipids) in a composition of the present invention is preferably from about 6:1 to about 1:1 nucleic acid:lipid by weight; and more preferably, from about 6:1 to 1:10. Complexing a POMC peptide or analog thereof with a liposome is similarly achieved using methods standard in the art.

10 An appropriate single dose of a nucleic acid:liposome complex of the present invention is from about 0.1 μg to about 100 μg per kg body weight of the mammal to which the complex is being administered. Preferably, an appropriate single dose of a nucleic acid:liposome complex of the present invention results in at least about 1 pg of protein expressed per mg of total tissue protein per μg of nucleic acid delivered. More
15 preferably, an appropriate single dose of a nucleic acid:liposome complex of the present invention is a dose which results in at least about 10 pg of protein expressed per mg of total tissue protein per μg of nucleic acid delivered; and even more preferably, at least about 50 pg of protein expressed per mg of total tissue protein per μg of nucleic acid delivered; and most preferably, at least about 100 pg of protein expressed per mg of total
20 tissue protein per μg of nucleic acid delivered.

In accordance with the present invention, a suitable or effective single dose size is a dose that is capable of causing a measurable change in the body weight (e.g., a decrease in body weight) of a patient when administered one or more times over a suitable time period. A suitable or effective single dose size can also be a dose that is capable of
25 causing a measurable change in the rate of weight gain or loss in a patient as compared to the rate established prior to initiation of the treatment, when administered one or more times over a suitable time period. In addition, a suitable or effective single dose size is a dose that is capable of preventing or effecting a measurable improvement in a condition in the patient that is associated with or caused by undesirable (e.g., medically unhealthy)
30 body weight. Such a condition includes, but is not limited to, cachexia, non-insulin dependent diabetes mellitus, cardiovascular disease, cancer, hypertension, osteoarthritis,

stroke, respiratory problems, reproductive dysfunction, mood disorders, heart problems, sarcopenia, wasting disease and/or gall bladder disease. According to the present invention, and as described previously herein, to regulate body weight can be any measurable decrease or increase in any factor related to body weight, including, but not
5 limited to actual body weight and/or size and changes in hormone levels or other biological indicators related to weight and metabolic control which indicate a change in body weight control, and particularly in hormone levels or other biological indicators related to central and/or peripheral melanocortinerbic and/or leptinerbic pathways of energy homeostasis. Doses can vary depending upon the condition of the patient being
10 treated, including the apparent cause of the body weight problem and/or any other related or non-related health factors experienced by a particular patient. In general, a patient who has greater excess body weight relative to another patient, may actually require a smaller dose of a POMC compound to obtain an effect from the treatment. In one embodiment of the present invention, formulations derived from POMC compounds are utilized to
15 either increase or decrease adipose tissue in a nonobese or relatively normal individual (e.g., for cosmetic purposes). This can be accomplished by modifying the normal fat metabolism of an individual through the administration of suitable amounts of modified forms of the present composition (e.g., POMC homologues, mimetics, etc.).

One embodiment of the method of the present invention comprises administering
20 a POMC compound, and particularly, a POMC homologue or mimetic, in a dose, concentration and for a time sufficient to effect a measurable change in the body weight or mass of a patient. Such a compound is administered in a dose between a minimum amount sufficient to reach the systemic circulation in the patient and to obtain a measurable effect on body weight or mass in a patient, a dose which minimizes delivery
25 to the central nervous system, and a maximum amount which is effective to obtain a measurable effect on body weight or mass in a patient without inducing deleterious effects (e.g., unmanageable toxicity) in the patient. More particularly, the method of the present invention comprises administering a POMC compound, and particularly, a POMC homologue or mimetic, in a dose between about 0.1 μ g and about 100 mg per kilogram
30 body weight of the patient, and preferably, between about 0.1 μ g and about 10 mg per kilogram body weight of the patient, and more preferably, between about 0.1 μ g and

about 1 μg per kilogram body weight of the patient, and even more preferably, between about 1 μg and about 10 mg per kilogram body weight of the patient. A more preferred single dose is from about 40 μg to about 1 mg per kilogram body weight of the patient. A typical daily dose for an adult human (i.e., a 75kg human) is from about 1 milligram to about 100 milligrams. A preferred circulating level of a POMC compound to achieve in a patient regardless of the route of administration is from about 0.1 μg per kilogram body weight to about 10 μg per kilogram body weight, and more preferably, from about 0.1 μg per kilogram body weight to about 1 μg per kilogram body weight of the patient. In practicing this method, the POMC compound or therapeutic composition containing the compound can be administered in a single daily dose or in multiple doses per day. This treatment method may require administration over extended periods of time. The amount per administered dose or the total amount administered will be determined by the physician and will depend on such factors as the mass of the patient, the age and general health of the patient and the tolerance of the patient to the compound. As discussed above, the molar concentration of a melanocortin agonist that would be necessary to effect a transient decrease in food intake (i.e., via the central nervous system and the melanocortin 4-receptor) is *one hundred-fold higher* than that required to accomplish weight reduction via peripheral mechanisms (lipolysis and fatty acid uptake). The above doses are believed to sufficient to affect the peripheral metabolic efficiency (i.e., peripheral energy homeostasis) while minimizing effects on the central nervous system and particularly, appetite.

One embodiment of the present invention relates to a method to treat a patient who is unable to gain or retain weight. Such a method includes the step of administering to the periphery of a patient a POMC compound, and preferably, a homologue or mimetic of a POMC peptide, such compound having reduced biological activity as compared to the naturally occurring POMC peptide (i.e., prototype) upon which the homologue or mimetic is based. Such a compound, also referred to herein as a POMC peptide antagonist, is effective to increase the body weight of the patient by a mechanism which can include: blocking the action of the endogenous peptide, for example by binding to and blocking the receptor for the endogenous peptide; or by stimulating free fatty acid uptake and/or inhibiting lipolysis. Other aspects of such a method, including compound

preparation and administration are as described for other POMC compounds described previously herein.

Yet another embodiment of the present invention relates to a method to selectively increase or decrease adipose tissue in a specific portion of the body of a patient, comprising introducing to said animal by localized and/or targeted delivery a therapeutic composition of the present invention. Other aspects of such a method, including compound preparation and administration are as described for other POMC compounds described previously herein.

Another embodiment of the present invention relates to a method for inhibition of free fatty acid uptake and/or stimulation of lipolysis in an animal, comprising administering to the periphery of an animal a POMC compound in an amount effective to produce a result selected from the group consisting of stimulation of lipolysis and inhibition of fatty acid uptake. Various aspects of such a method, including compound preparation and administration are as described for other POMC compounds described previously herein. Inhibition of free fatty acid uptake and/or stimulation of lipolysis can be measured by methods known in the art. Preferably, free fatty acid uptake is measurably inhibited as compared to the level of free fatty acid uptake prior to administration of the compound and lipolysis is measurably stimulated as compared to the level of lipolysis prior to administration of the compound. Preferably, the amount of POMC compound administered is insufficient to cause a statistically significant change in the appetite of the animal after administration of the compound as compared to before administration of the compound.

Yet another embodiment of the present invention relates to a method of regulating the body weight of an animal, comprising administering to an animal a POMC compound in an amount effective to bind to POMC receptors expressed by the animal in the animal's peripheral tissues. The effective amount is defined as: (a) being insufficient to substantially change the appetite of the animal after the step of administering as compared to before the step of administering; (b) being between about 0.1 μ g and about 10 mg per kg of body weight of the animal; (c) being sufficient to affect a biological activity selected from the group consisting of: (i) lipolysis; and, (ii) uptake of fatty acids by adipocytes in the animal; and, (d) being effective to measurably increase or decrease the body weight

of the animal after the compound has been administered to the animal. Aspects of such a method, including compound preparation and administration are as described for other POMC compounds described previously herein.

Another embodiment of the present invention relates to a method to regulate body weight in an animal, comprising modulating the activity of a melanocortin receptor selected from the group consisting of melanocortin 2-receptor and melanocortin 5-receptor. Preferably, the melanocortin receptor is melanocortin 2-receptor. In one embodiment, the step of modulating includes, but is not limited to, administering to the periphery of the animal a compound which regulates the melanocortin receptor. The compound can include, but is not limited to, a POMC compound, an antibody that selectively binds to the melanocortin receptor, and a soluble melanocortin receptor. In another aspect, the step of modulating comprises administering an effective amount of a compound that increases expression of the melanocortin 2-receptor and induces weight loss. In another aspect, the step of modulating comprises administering an effective amount of a compound that decreases expression of the melanocortin 2-receptor and induces weight gain. Aspects of such a method, including various types of receptor agonists and antagonists and compound preparation and administration are as described previously herein.

Yet another embodiment of the present invention relates to a method for regulating metabolic efficiency in an animal, comprising: (a) measuring serum MSH levels in an animal; (b) identifying animals having serum MSH levels of less than about 0.1 ng/ml; and, (c) administering to the periphery of the animals identified in (b) a composition comprising a compound selected from the group consisting of a POMC compound and leptin. Preferably, the compound is administered in an amount effective to increase serum MSH levels in the animal to level effective to produce a result selected from the group consisting of stimulating lipolysis and inhibiting fatty acid uptake in the animal. In one embodiment, the compound is administered in an amount effective to produce a measurable decrease in body weight of the animal. In a preferred embodiment, the compound is administered in an amount effective to increase serum MSH levels to those established for a normal population of patients, which for humans, in one embodiment, is about 0.15 ng/ml or higher.

Another embodiment of the present invention relates to a therapeutic composition useful in any of the above-described or below-described embodiments of the method of the present invention. A therapeutic composition of the present invention comprises one or more therapeutic compounds, including at least one POMC compound as described
5 herein, formulated with a pharmaceutically acceptable carrier. In a preferred embodiment, a therapeutic composition of the present invention includes at least one POMC compound and at least one other body weight regulating compound. In one embodiment, such another body weight regulating compound can include, but is not limited to, leptin.

Preferably, if the additional body weight regulating agent is leptin, the method of
10 the present invention includes administering a leptin compound, including a leptin homologue or mimetic, in conjunction with a POMC compound, in a dose, concentration and for a time sufficient to effect a measurable change in the body weight or mass of a patient. Such a compound is administered in a dose between a minimum amount sufficient to reach the systemic circulation in the patient and to obtain a measurable effect on body
15 weight or mass in a patient, and a maximum amount which is effective to obtain a measurable effect on body weight or mass in a patient without inducing deleterious effects (e.g., unmanageable toxicity) in the patient. More particularly, the method of the present invention comprises administering a leptin compound in a dose between about 0.1 μ g and about 100 mg per kilogram body weight of the patient, and preferably, between about 0.1
20 μ g and about 10 mg per kilogram body weight of the patient, and more preferably, between about 0.1 μ g and about 1 μ g per kilogram body weight of the patient, and even more preferably, between about 1 μ g and about 10 mg per kilogram body weight of the patient. A more preferred single dose is from about 50 μ g to about 1 mg per kilogram body weight of the patient. A typical daily dose for an adult human (i.e., a 75kg human)
25 is from about 0.5 milligram to about 100 milligrams. In practicing this method, the leptin compound or therapeutic composition containing the POMC compound and the leptin compound can be administered in a single daily dose or in multiple doses per day. This treatment method may require administration over extended periods of time. The amount per administered dose or the total amount administered will be determined by the
30 physician and will depend on such factors as the mass of the patient, the age and general health of the patient and the tolerance of the patient to the compound. As discussed

above, preferably, the ratio of MSH to leptin in the composition is about 1:100, and more preferably, about 1:25 and even more preferably, about 1:10.

One embodiment of the present invention relates to a method to identify compounds which regulate body weight in an animal, and particularly, compounds useful
5 in any of the methods of the present invention as described herein. In a preferred embodiment, the present methods are useful for identifying homologues and mimetics of POMC compounds, for use in a therapeutic method of the present invention. Such a method includes screening a putative regulatory compound (i.e., a test compound) for its ability to stimulate lipolysis and/or to inhibit fatty acid uptake by adipocytes, and in
10 particular, to control obesity. Such a method includes selecting compounds which preferentially bind to and/or activate peripheral melanocortin receptors as compared to central nervous system melanocortin receptors, and particularly, MC4-R. Such a method can be performed *in vitro* or *in vivo* (e.g., *in vivo* experiments can be performed using the POMC mutant mouse model of obesity of the present invention, and the compounds
15 identified by such a method can be used in the method to treat obesity according to the present invention).

More particularly, one aspect of this method of the present invention is a method for identifying compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. Such a method includes the steps of: (a) contacting a
20 putative regulatory compound with a cell which expresses a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting whether the putative regulatory compound increases the melanocortin receptor activity; (c) contacting the putative regulatory compound with a cell which expresses a melanocortin 4-receptor (MC4-R); and, (d) detecting whether the
25 putative regulatory compound increases MC4-R activity. In this method, putative regulatory compounds that induce greater MC2-R activity or MC5-R activity as compared to MC4-R activity are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor of (a) and (b) is MC2-R.

30 Another aspect of the invention relates to a method for identifying compounds that increase body weight by regulating peripheral pathways of energy homeostasis,

comprising: (a) contacting a cell which expresses a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates the melanocortin receptor, in the presence and absence of a putative regulatory compound; and (b)
5 detecting whether the putative regulatory compound inhibits the melanocortin receptor activity. In this embodiment, putative regulatory compounds that inhibit the melanocortin receptor activity are identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R. In another embodiment, the putative regulatory compound is further
10 evaluated for its ability to regulate body weight in an *in vivo* model of body weight regulation, such by peripheral administration of the compound to the *pomc/pomc* mouse described herein. The POMC compound can include, but is not limited to a melanocortin compound, including α -MSH, β -MSH and γ -MSH.

In another aspect, the method is a method for identifying compounds that regulate
15 body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell which expresses a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting whether the putative regulatory compound binds to the melanocortin receptor; and, (c) administering compounds which
20 bind to the melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of the test animal. In this aspect, putative regulatory compounds that bind to the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which regulate body weight by regulating peripheral pathways of energy homeostasis. In a preferred
25 embodiment, the melanocortin receptor is MC2-R. The test animal can be, for example, but is not limited to, a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein the genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in the animal.

Yet another aspect of the method is a method for identifying compounds that
30 increase body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a cell which expresses a melanocortin receptor selected from

the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates the melanocortin receptor, in the presence and absence of a putative regulatory compound; (b) detecting whether the POMC compound binds to the melanocortin receptor; (c) administering
5 compounds which bind to the melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of the test animal. In this aspect, putative regulatory compounds that bind to the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which increase body weight by regulating peripheral pathways of energy homeostasis. In
10 a preferred embodiment, the melanocortin receptor is MC2-R.

Another aspect of the method is a method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a melanocortin receptor selected
15 from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); (b) detecting expression of the reporter gene product; (c) contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a melanocortin 4-receptor (MC4-R); and, (d) detecting expression of the reporter gene product. In this aspect, putative
20 regulatory compounds that increase expression of the reporter gene product of (b) as compared to the reporter gene product of (d) are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

Yet another aspect of this method is a method for identifying compounds that
25 regulate body weight by regulating peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with a cell or cell lysate containing transcripts of a melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); and, (b) detecting translational inhibition of the melanocortin receptor transcript. In this aspect,
30 putative regulatory compounds that inhibit the melanocortin receptor transcript are

identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

Another aspect of this method is a method for identifying compounds that regulate peripheral pathways of energy homeostasis, comprising: (a) contacting a putative regulatory compound with an isolated adipocyte; and, (b) detecting putative regulatory compounds that bind to a melanocortin receptor on the adipocyte, wherein putative regulatory compounds that bind to melanocortin receptors on the adipocytes are identified as compounds that regulate body weight by regulating peripheral pathways of energy homeostasis. The step of detecting can further comprise detecting putative regulatory compounds which produce a result selected from the group consisting of stimulation of lipolysis in the adipocytes and inhibition of the uptake of fatty acids by the adipocytes, wherein putative regulatory compounds that bind to melanocortin receptors on the adipocytes and that produce the result are identified as compounds that regulate body weight by regulating peripheral pathways of energy homeostasis. In a preferred embodiment, the melanocortin receptor is MC2-R.

It is noted that melanocortin receptor genes and proteins, and *in vitro* assays for determining melanocortin receptor activity are known in the art. For example, U.S. Patent Nos. 5,703,220 and 5,710,265 to Yamada et al.; U.S. Patent No. 5,532,347 to Cone et al.; and PCT Publication WO 97/47316 and U.S. Patent Nos. 5,908,609 and 5,932,779 to Lee et al.; describe known melanocortin receptors and the genes encoding such receptors, including MC2-R, MC4-R and MC5-R, as well as *in vitro* and *in vivo* assays for identifying compounds which bind to and/or activate such receptors. Each of these patents and PCT publication is incorporated herein by reference in its entirety, and particularly, with regard to disclosed methods for evaluating the activity of melanocortin receptors and the identification of compounds which bind to such receptors. However, none of the above-referenced patents or PCT publication discloses a method for identifying compounds useful for regulating body weight by identifying compounds which bind to, activate or inhibit activity of peripheral melanocortin receptors, and particularly, which preferentially bind to, activate or inhibit activity over central melanocortin receptors. Indeed, it is particularly noted that although the patents and PCT publication of Lee et al. are directed to identifying compounds for regulation of body weight, the

target receptor of Lee et al. (i.e., MC4-R) is *directly opposite* of the target receptors of the present invention (i.e., MC2-R and/or MC5-R), since the methods of Lee et al. target the central mechanisms of energy homeostasis (e.g., appetite), while the present invention targets the peripheral mechanisms of energy homeostasis (e.g., lipolysis and/or free fatty acid uptake). Prior to the present invention, it was not known that the peripheral melanocortin receptors (and not central melanocortin receptors) and the compounds that bind to such receptors regulate metabolic efficiency. Moreover, the present inventors are the first to disclose an assay for the identification of compounds that preferentially bind to, activate, or inhibit the activity of MC2-R and/or MC5-R as compared to MC4-R, or which bind to, activate, or inhibit the activity of MC2-R and/or MC5-R in the absence of significant MC4-R binding or activation.

According to the present invention, the “activity” or “biological activity” of a melanocortin receptor refers to any function(s) exhibited or performed by a naturally occurring form of the melanocortin receptor as measured or observed *in vivo* (i.e., in the natural physiological environment of the protein) or *in vitro* (i.e., under laboratory conditions). For example, a biological activity of a melanocortin receptor can include, but is not limited to, ligand binding activity (e.g., with a melanocortin, such as MSH), G protein activation, interaction with an intracellular signal transduction protein, upregulation of expression of the melanocortin receptor, and induction of biological effects such as lipolysis and/or free fatty acid uptake (for peripheral receptors) and modulation of appetite (*in vivo* for MC4-R). An increase in melanocortin receptor activity can be referred to as amplification, overproduction, activation, enhancement, up-regulation or increased action of the receptor, as compared to a normal or baseline control or as compared to the activity of the receptor prior to a given treatment (e.g., contact with a putative regulatory compound). Similarly, a decrease in melanocortin receptor activity can be referred to as inactivation (complete or partial), inhibition, down-regulation, or decreased action of the receptor, as compared to a normal or baseline control or as compared to the activity of the receptor prior to a given treatment (e.g., contact with a putative regulatory compound).

According to the present method, in some embodiments, the binding of a compound to a peripheral melanocortin receptor (e.g., MC2-R or MC 5-R) is compared

to the binding of the same compound to a central melanocortin receptor (e.g., MC4-R). The binding of the compound to different receptors can be compared by evaluating the binding affinity or the avidity of the compound for the receptor using binding assays that are well known and standard in the art, and comparing the results. A difference in binding
5 of a compound to one receptor as compared to another is determined as any statistically significant difference in the binding affinity or avidity as determined by the same method of evaluation for each receptor. The difference can be an increase or decrease in binding affinity or avidity of a test compound to one receptor as compared to a different receptor. Preferably, a regulatory compound that binds to an MC2-R and/or an MC5-R binds to
10 such receptors with at least a 10 fold greater affinity or avidity as compared to binding to an MC4-R, and more preferably, at least a 100 fold greater affinity or avidity, and more preferably, at least a 1000 fold greater affinity or avidity and even more preferably, at least a 10,000 fold greater affinity or avidity as compared to binding of the same compound to an MC4-R.

15 In other embodiments, the activity of a peripheral melanocortin receptor as a result of interaction with a compound is compared to the activity of a central melanocortin receptor as a result of interaction with the same compound. Activity of the receptor can be measured by any method, such as those described in the above-identified patents and PCT publication, and include, but are not limited to, methods of measuring: melanocortin
20 receptor transcription, melanocortin receptor translation, phosphorylation of melanocortin receptor, melanocortin receptor ligand binding activity, melanocortin receptor translocation within a cell, interaction of the receptor with an intracellular signal transduction protein, and induction of biological effects such as lipolysis and/or free fatty acid uptake (for peripheral receptors) and modulation of appetite (*in vivo* for MC4-R).
25 Preferably, a regulatory compound useful for body weight loss or decrease in weight gain (including prevention of weight gain, or maintenance of weight) induces or increases the activity of an MC2-R and/or an MC5-R at least about 10 fold more as compared to the activity of an MC4-R contacted with the same compound, and preferably, at least about 100 fold more, and more preferably, at least about 1000 fold more, and even more
30 preferably, at least about 10,000 fold more as compared to the activity of an MC4-R contacted with the same compound. A regulatory compound useful for body weight gain

or decrease in weight loss (including prevention of weight loss, or maintenance of weight), preferably inhibits the activity of a MC2-R and/or an MC5-R, and in some embodiments, inhibits the activity of MC2-R and/or an MC5-R at least about 10 fold more, and preferably at least about 100 fold more, and more preferably, at least about 1000 fold more, and even more preferably, at least about 10,000 fold more as compared to the activity of an MC4-R contacted with the same compound.

As used herein, the term "putative" refers to compounds having an unknown or previously unappreciated regulatory activity in a particular process. As such, the term "identify" is intended to include all compounds, the usefulness of which as a regulatory compound of melanocortin activity for the purposes of regulating body weight through peripheral mechanisms of energy homeostasis is determined by a method of the present invention.

The methods of the present invention include contacting a test cell or a cell lysate with a compound being tested for its ability to bind to and/or regulate the activity of a melanocortin receptor. For example, test cells can be grown in liquid culture medium or grown on solid medium in which the liquid medium or the solid medium contains the compound to be tested. In addition, as described above, the liquid or solid medium contains components necessary for cell growth, such as assimilable carbon, nitrogen and micro-nutrients.

The present methods involve contacting cells with the compound being tested for a sufficient time to allow for interaction, activation or inhibition of the receptor by the compound. The period of contact with the compound being tested can be varied depending on the result being measured, and can be determined by one of skill in the art. For example, for binding assays, a shorter time of contact with the compound being tested is typically suitable, than when activation is assessed. As used herein, the term "contact period" refers to the time period during which cells are in contact with the compound being tested. The term "incubation period" refers to the entire time during which cells are allowed to grow prior to evaluation, and can be inclusive of the contact period. Thus, the incubation period includes all of the contact period and may include a further time period during which the compound being tested is not present but during which growth is continuing (in the case of a cell based assay) prior to scoring. The incubation time for

growth of cells can vary but is sufficient to allow for the binding of the melanocortin receptor, activation of the receptor, and/or inhibition of the receptor. It will be recognized that shorter incubation times are preferable because compounds can be more rapidly screened. A preferred incubation time is between about 1 minute to about 48 hours.

5 The conditions under which the cell or cell lysate of the present invention is contacted with a putative regulatory compound, such as by mixing, are any suitable culture or assay conditions and includes an effective medium in which the cell can be cultured or in which the cell lysate can be evaluated in the presence and absence of a putative regulatory compound.

10 Cells of the present invention can be cultured in a variety of containers including, but not limited to, tissue culture flasks, test tubes, microtiter dishes, and petri plates. Culturing is carried out at a temperature, pH and carbon dioxide content appropriate for the cell. Such culturing conditions are also within the skill in the art. Acceptable protocols to contact a cell with a putative regulatory compound in an effective manner
15 include the number of cells per container contacted, the concentration of putative regulatory compound(s) administered to a cell, the incubation time of the putative regulatory compound with the cell, and the concentration of compound administered to a cell. Determination of such protocols can be accomplished by those skilled in the art based on variables such as the size of the container, the volume of liquid in the container,
20 the type of cell being tested and the chemical composition of the putative regulatory compound (i.e., size, charge etc.) being tested. A preferred amount of putative regulatory compound(s) comprises between about 1 nM to about 10 mM of putative regulatory compound(s) per well of a 96-well plate.

 Suitable cells for use with the present invention include any cell that has
25 endogenously expresses a melanocortin receptor as disclosed herein, or which has been transfected with and expresses recombinant melanocortin receptor as disclosed herein (such as 293 cells, COS cells, CHO cells, fibroblasts, etc., genetically engineered to express the melanocortin receptor). In one embodiment, host cells genetically engineered to express a functional receptor that responds to activation by POMC peptides can be
30 used as an endpoint in the assay; *e.g.*, as measured by a chemical, physiological, biological, or phenotypic change, induction of a host cell gene or a reporter gene, change in cAMP

levels, adenylyl cyclase activity, host cell G protein activity, extracellular acidification rate, host cell kinase activity, proliferation, differentiation, etc. Cells for use with the present invention include mammalian, invertebrate, plant, insect, fungal, yeast and bacterial cells. Preferred cells include mammalian, amphibian and yeast cells. Preferred mammalian cells include primate, non-human primate, mouse and rat, with human cells being preferred. A particularly preferred cell which expressed MC2-R and/or MC5-R is an adipocyte. In one embodiment, compounds may be identified which increase the activity of mutant melanocortin receptor, thereby alleviating the symptoms of body weight disorders arising from mutant peripheral receptors.

Preferably, the test cell (host cell) should express a functional melanocortin receptor that gives a significant response to a POMC compound that is known to bind to and activate the melanocortin receptor, preferably greater than 2, 5, or 10-fold induction over background. As disclosed in U.S. Patent Nos. 5,908,609 and 5,932,779, *supra*, host cells can possess a number of characteristics, depending on the readout, to maximize the inductive response by compounds, for example, for detecting a strong induction of a CRE reporter gene: (a) a low natural level of cAMP, (b) G proteins capable of interacting with the melanocortin receptor, (c) a high level of adenylyl cyclase, (d) a high level of protein kinase A, (e) a low level of phosphodiesterases, and (f) a high level of cAMP response element binding protein would be advantageous. To increase response to melanocortin peptide, host cells could be engineered to express a greater amount of favorable factors or a lesser amount of unfavorable factors. In addition, alternative pathways for induction of the CRE reporter could be eliminated to reduce basal levels.

When the cell is additionally contacted with a POMC compound that binds to and activates the melanocortin receptor, such a POMC compound can be any POMC compound as described elsewhere herein. The POMC compound can be contacted with the melanocortin receptor (or the cell expressing such receptor) prior to, simultaneous with, or after contact of the putative regulatory compound with the cell, depending on how the assay is to be evaluated, and depending on whether activation or inhibition of the receptor is to be evaluated. In one embodiment, the POMC compound is contacted with the receptor after the cell is contacted with the putative regulatory compound so that the test compound can be evaluated for its ability to inhibit activation of the receptor by the

POMC compound. In another embodiment, when binding is to be evaluated, the POMC compound can be contacted with the receptor at the same time as the test compound. Preferably, the POMC compound is contacted with the cell/receptor in the presence and absence of the test compound for a controlled assay.

5 As discussed above, the step of detecting whether a putative regulatory compound binds to, activates and/or inhibits a test cell can be performed by any suitable method, including, but not limited to measurement of melanocortin receptor transcription, measurement of melanocortin receptor translation, measurement of phosphorylation of melanocortin receptor, measurement of melanocortin receptor ligand binding activity, and
10 measurement of melanocortin receptor translocation within a cell. When the cell is an adipocyte, the step of detecting can further include measurement of lipolysis by the cell and measurement of free fatty acid uptake by the cell. Such methods of detecting an interaction of a ligand with a receptor, including the interaction of a ligand with a melanocortin receptor, are known in the art as discussed above, and include immunoblots,
15 phosphorylation assays, kinase assays, immunofluorescence microscopy, RNA assays, immunoprecipitation, and other biological assays. Cell lysates can be assayed, for example for induction of cAMP (See U.S. Patent Nos. 5,908,609 and 5,932,779). The ability of a test compound to increase levels of cAMP, above those levels seen with cells treated with a vehicle control, indicates that the test compound induces signal transduction
20 mediated by the melanocortin receptor expressed by the host cell. Methods to determine whether a test compound affects lipolysis and/or free fatty acid uptake by an adipocyte are known in the art. For example, lipolysis assays are described in Rodbell, 1964, *J. Biol. Chem.* 239:375-380 and in Dole et al., 1960, *J. Biol. Chem.* 235:2595-2599, each of which is incorporated herein by reference in its entirety. Fatty acid uptake assays are
25 described in Schwieterman et al., 1988, *Proc. Natl. Acad. Sci. U.S.A.* 85:359-363, also incorporated herein by reference in its entirety.

 To determine intracellular cAMP concentrations, a scintillation proximity assay (SPA) may be utilized (SPA kit is provided by Amersham Life Sciences, Illinois). The assay utilizes ¹²⁵I label cAMP, an anti-cAMP antibody, and a scintillant-incorporated
30 microsphere coated with a secondary antibody. When brought into close proximity to the microsphere through the labeled cAMP-antibody complex, ¹²⁵I will excite the scintillant

to emit light. Unlabeled cAMP extracted from cells competes with the ^{125}I -labeled cAMP for binding to the antibody and thereby diminishes scintillation. The assay may be performed in 96-well plates to enable high-throughput screening and 96 well-based scintillation counting instruments such as those manufactured by Wallac or Packard may be used for readout.

In a specific embodiment of the invention, constructs containing the cAMP responsive element linked to any of a variety of different reporter genes may be introduced into cells expressing the melanocortin receptor. Such reporter genes may include, but is not limited to, chloramphenicol acetyltransferase (CAT), luciferase, GUS, growth hormone, or placental alkaline phosphatase (SEAP). Following exposure of the cells to the test compound, the level of reporter gene expression may be quantitated to determine the test compound's ability to regulate receptor activity. Alkaline phosphatase assays are particularly useful in the practice of the invention as the enzyme is secreted from the cell. Therefore, tissue culture supernatant may be assayed for secreted alkaline phosphatase. In addition, alkaline phosphatase activity may be measured by calorimetric, bioluminescent or chemiluminescent assays such as those described in Bronstein, I. et al., (1994, *Biotechniques* 17:172-177). Such assays provide a simple, sensitive easily automatable detection system for pharmaceutical screening.

When it is desired to discriminate between the melanocortin receptors and to identify compounds that selectively agonize or antagonize the peripheral receptors (e.g., MC2-R and/or MC5-R), particularly to a significantly greater degree than the MC4-R, the assays described above should be conducted using a panel of host cells, each genetically engineered to express one of the melanocortin receptors (MC1-R through MC5-R). Host cells can be genetically engineered to express any of the amino acid sequences known for melanocortin receptors in the art. Preferably, when comparing receptor binding and/or activity in response to contact with a putative regulatory compound, the cell type is essentially the same for each receptor (e.g., a panel of fibroblasts from the same fibroblast cell line recombinantly expressing the various receptors). As disclosed by U.S. Patent Nos. 5,908,609 and 5,932,779, the cloning and characterization of each receptor has been described: MC1-R and MC2-R (Mountjoy, 1992, *Science*, 257:1248-1251; Chhajlani & Wikberg, 1992, *FEBS Lett.*, 309:417-420); MC3-R (Roselli-Rehfuss et al., 1993, *Proc.*

Natl. Acad. Sci. USA, 90:8856-8860; Gantz et al., 1993, *J. Biol. Chem.*, 268:8246-8250); MC4-R (Gantz et al., 1993, *J. Biol. Chem.*, 268:15174-15179; Mountjoy et al., 1994, *Mol. Endo.*, 8:1298-1308); and MC5-R (Chhajlani et al., 1993, *Biochem. Biophys. Res. Commun.*, 195:866-873; Gantz et al., 1994, *Biochem. Biophys. Res. Commun.*, 200:1214-1220), each of which is incorporated by reference herein in its entirety. Thus, each of the foregoing sequences can be utilized to engineer a cell or cell line that expresses one of the melanocortin receptors for use in screening assays described herein. To identify compounds that specifically or selectively regulate peripheral melanocortin receptor activity, the activation, or inhibition of peripheral melanocortin receptors is compared to the effect of the test compound on the other melanocortin receptors, and particularly, the central receptors (e.g., MC4-R).

As disclosed above, the present methods also make use of non-cell based assay systems to identify compounds that can regulate the peripheral mechanisms of energy homeostasis. Such methods are again described for targeting MC4-R, for example, in U.S. Patent Nos. 5,908,609 and 5,932,779. For example, isolated membranes may be used to identify compounds that interact with the melanocortin receptor being tested. Membranes can be harvested from cells expressing melanocortin receptors by standard techniques and used in an *in vitro* binding assay. ¹²⁵I-labeled ligand (e.g., ¹²⁵I-labeled α -MSH, β -MSH, or ACTH) is bound to the membranes and assayed for specific activity; specific binding is determined by comparison with binding assays performed in the presence of excess unlabeled ligand. Membranes are typically incubated with labeled ligand in the presence or absence of test compound. Compounds that bind to the receptor and compete with labeled ligand for binding to the membranes reduced the signal compared to the vehicle control samples.

Alternatively, soluble melanocortin receptors may be recombinantly expressed and utilized in non-cell based assays to identify compounds that bind to melanocortin receptors. Recombinantly expressed melanocortin receptor polypeptides or fusion proteins containing one or more extracellular domains of melanocortin receptor can be used in the non-cell based screening assays. Alternatively, peptides corresponding to one or more of the cytoplasmic domains of the melanocortin receptor or fusion proteins containing one or more of the cytoplasmic domains of the melanocortin receptor can be

used in non-cell based assay systems to identify compounds that bind to the cytoplasmic portion of the melanocortin receptor; such compounds may be useful to modulate the signal transduction pathway of the melanocortin receptor. In non-cell based assays the recombinantly expressed melanocortin receptor is attached to a solid substrate such as a test tube, microtitre well or a column, by means well known to those in the art. The test compounds are then assayed for their ability to bind to the melanocortin receptor.

As discussed above, *in vitro* cell based assays may be designed to screen for compounds that regulate melanocortin receptor expression at either the transcriptional or translational level. In one embodiment, DNA encoding a reporter molecule can be linked to a regulatory element of the melanocortin receptor gene and used in appropriate intact cells, cell extracts or lysates to identify compounds that modulate melanocortin receptor gene expression. Appropriate cells or cell extracts are prepared from any cell type that normally expresses the melanocortin receptor gene, thereby ensuring that the cell extracts contain the transcription factors required for *in vitro* or *in vivo* transcription. The screen can be used to identify compounds that modulate the expression of the reporter construct. In such screens, the level of reporter gene expression is determined in the presence of the test compound and compared to the level of expression in the absence of the test compound.

To identify compounds that regulate melanocortin receptor translation, cells or *in vitro* cell lysates containing melanocortin receptor transcripts may be tested for modulation of melanocortin receptor mRNA translation. To assay for inhibitors of melanocortin receptor translation, test compounds are assayed for their ability to modulate the translation of melanocortin receptor mRNA in *in vitro* translation extracts. Compounds that decrease the level of peripheral melanocortin receptor expression (i.e., MC2-R and/or MC5-R), either at the transcriptional or translational level, may be useful for treatment of body weight disorders such as anorexia and cachexia. In contrast, those compounds that increase the expression of such peripheral receptors may be useful for treatment of disorders such as obesity.

Finally, a putative regulatory compound of the present invention can be evaluated by administering putative regulatory compounds to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of the test

animal. Preferred modes of administration, including dose, route and other aspects of the method are as previously described herein for the therapeutic methods of the present invention. The test animal can be any suitable non-human animal, including any test animal described herein or in the art for examination of the regulation of body weight.

5 The test animal can be, for example, but is not limited to, a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein the genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in the animal. Such an animal and additional *in vivo* assay methods for using such an animal are disclosed in copending U.S. Application Serial No. 09/374,827,
10 filed August 12, 1999, incorporated herein by reference in its entirety.

Another embodiment of the present invention relates to a method to treat health-compromising conditions associated with excess body weight, and particularly, obesity. Such conditions include, but are not limited to, non-insulin dependent diabetes mellitus (NIDDM), cardiovascular disease, cancer, hypertension, osteoarthritis, stroke, respiratory
15 problems and gall bladder disease. Such a method includes the step of administering to the periphery of an animal suffering from or at risk for developing an obesity-associated condition, a therapeutic composition comprising a POMC compound which can include POMC peptides or fragments, homologues, peptide mimetics, non-peptide mimetics, fusion proteins or pharmaceutically acceptable salts thereof; or, recombinant nucleic acid
20 molecules encoding such POMC peptides, fragments, homologues, peptide mimetics, or fusion proteins. The POMC compound is administered peripherally in an amount effective measurably decrease body weight or the rate of weight gain, and/or to reduce or prevent the deleterious symptoms of the health-compromising condition. The POMC compound of the present invention can be administered with or without one or more additional
25 compounds, including other body weight regulating compounds, such as leptin. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

As used herein, the an obesity-associated disorder is any disease or condition that is caused by or associated with (e.g., by biochemical or molecular association) obesity or
30 that is caused by or associated with weight gain and/or related biological processes that precede clinical obesity. The phrase, "to treat" a disorder associated with obesity in a

patient refers to reducing, ameliorating or preventing the disorder in a patient that suffers from the disorder or is at risk of acquiring the disorder. Therefore, in one embodiment of the present invention, "to treat" a disorder associated with obesity can also mean "to prevent" the disorder in a patient. Preferably, the disorder, or the potential for developing the disorder, is reduced, optimally, to an extent that the patient no longer suffers from or does not develop the disorder or the discomfort and/or altered functions and detrimental conditions associated with such disorder. The method of the present invention includes the administration of POMC compounds as disclosed herein to prevent the onset of the symptoms or complications associated with undesired body weight and the metabolic dysfunction of obesity, to alleviate the symptoms or complications of the obesity-related disorder other than, or in addition to, obesity, or to eliminate the obesity-related disorder. Therefore, treatment of an obesity-associated disorder can also include regulation of body weight for treatment of the obesity itself, which is likely to indirectly concurrently improve the obesity-related disorder.

The method of the present invention, being directed to the treatment of a disorder that is associated with obesity, is intended to be used in conjunction with one or more other treatment protocols that are appropriate for treatment of the given condition. For example, for a patient that has NIDDM, in addition to administering the therapeutic composition of the present invention, the patient may be treated with a regimen of diet and exercise, and in extreme cases, with injections of insulin.

According to the present invention, an effective administration protocol (i.e., administering a POMC compound or a therapeutic composition comprising such a compound in an effective manner) comprises suitable dose parameters and modes of administration that result in a measurable change in one or more symptoms of the condition associated with obesity that is to be treated. For example, a patient with NIDDM, after treatment with a therapeutic composition of the present invention, may experience an increased ability to regulate blood glucose levels, as indicated by an improved score in a standard glucose tolerance test. Preferably, an effective administration protocol comprises suitable dose parameters and modes of administration that also result in the regulation of body weight in the animal when administered one or more times over a suitable time period. Effective dose parameters can be determined

using methods standard in the art for a particular animal and condition. Such methods include, for example, determination of survival rates, side effects (i.e., toxicity) and other health factors associated with, or in addition to the amount of body weight loss or gain desired in the animal. In particular, the effectiveness of dose parameters of a therapeutic composition of the present invention when used to control body weight can be determined by assessing response rates. Such response rates refer to the percentage of treated patients in a population of patients that respond with either partial or complete reduction in one or more symptoms of an obesity-associated condition and/or partial or complete loss of excess weight or a reduction in the rate of weight gain, to a level which is considered by those of skill in the art to be sufficient to address the needs of the particular patient and/or not present health risks to the patient. Response can be determined by, for example, measuring weight loss over time and/or measuring changes in levels of hormones and other biological indicators of obesity and the obesity-associated disorder in the animal, for example, leptin.

In a preferred embodiment, a therapeutic composition of the present invention includes at least one POMC compound and at least one other body weight regulating compound. In one embodiment, such another body weight regulating compound can include, but is not limited to, leptin. In another embodiment, a therapeutic composition of the present invention includes at least one POMC compound and at least one other compound that is useful in treating the obesity-associated disorder experienced by a patient. Such an additional compound could include, for example, insulin for an extremely severe case of NIDDM or a beta blocker for a patient with cardiovascular disease.

Another embodiment of the present invention relates to compositions and methods for treating affective and mood disorders in an animal and for treating or preventing health-compromising conditions related thereto, and particularly, to regulate body weight in patients suffering from affective and mood disorders. As used herein, an affective and mood disorder, also referred to as an affective disorder, can be any disorder that is generally characterized by a neuroendocrine dysregulation and a disturbance in the regulation of mood, behavior and affect. Affective disorders can include major depressive disorders, such as depression and dysthymia, which atypical depression and dysthymia being particularly amenable to treatment using the present invention. According to the

present invention, "to treat" a disorder such as an affective and mood disorder can also mean "to prevent" the disorder in a patient. Preferably, the disorder, or the potential for developing the disorder, is reduced, optimally, to an extent that the patient no longer suffers from or does not develop the disorder, or the discomfort and/or altered functions and detrimental conditions associated with such disorder (e.g., sleeplessness, lack of energy, excessive accumulation of fat stores in adipose tissue). Such a method includes the step of peripherally administering to the patient a proopiomelanocortin (POMC) compound, which can include a POMC peptide, a fragment thereof, a homologue thereof, a peptide or non-peptide mimetic thereof, a fusion protein including such peptide, a pharmaceutically acceptable salt thereof, or a recombinant nucleic acid molecule encoding such a POMC peptide, fragment, homologue, peptide mimetic, or fusion protein thereof. In a preferred embodiment, the POMC compound is a melanocyte stimulating hormone (MSH) compound. The compound is administered in an amount effective to measurably ameliorate the disorder and/or to measurably regulate body weight in the animal, which minimizing delivery of the compound to the central nervous system. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

While a majority of the prior art methods to treat affective and mood disorders have involved the use of anti-depressant drugs or other compounds such as leptin (See U.S. Patent No. 5,866,547, *ibid.*), which regulate primarily the central nervous system, the present invention is directed to the use of compounds which regulate the *peripheral* pathways of energy homeostasis to treat affective and mood disorders and conditions related thereto, including dysregulation of body weight. Such a method comprises administering to an animal that is at risk for or has an affective and mood disorder and/or a detrimental condition related thereto a therapeutic composition that primarily regulates *the peripheral melanocortinerbic pathway and/or the leptinerbic pathway* of energy homeostasis. The compound and method of the present invention are believed to represent a new approach for the treatment of affective and mood disorders which are expected to have particular advantages for alleviating, eliminating or preventing undesirable symptoms associated with such disorders, such as excess or insufficient body weight.

More particularly, the present invention is derived from the inventors' discovery that administration of a proopiomelanocortin (POMC) peptide agonist to an animal suffering from obesity reduces obesity in the animal, from the present inventors' discovery that MSH and leptin synergize to enhance such a reduction, and from previous research
5 indicating a role for leptin in the treatment of affective and mood disorders (U.S. Patent No. 5,866,547, *ibid.*). Included in the present invention is a method for modifying the peripheral melanocortinerbic pathways for treating affective and mood disorders (and conditions related thereto) in patients at risk of, or suffering from such disorders, by administering an effective amount of circulating melanocyte stimulating hormone (MSH)
10 or analogs (e.g., homologues or mimetics) thereof, alone or in combination with leptin or other anti-depressant or body weight regulating drugs. In one embodiment of the present invention, POMC compounds, alone or in combination with leptin, are used to *enhance* the effects of a conventional treatment for affective and mood disorders, such as anti-depressant drugs and psychotherapy.

15 Affective and mood disorders are characterized by a wide fluctuation of moods, from extreme depression to elation. Such disorders are typically caused by neuroendocrine dysregulation and can have a deleterious and sometimes, incapacitating, effect on an individual's behavior and the ability of an individual to interact and function in every day life. Examples of such disorders include depression and dysthymia.

20 One type of depression, referred to herein as atypical depression, is characterized by decreased energy with hypersomnia, hyperphagia, weight gain and mood lability (Licinio et al., 1991, *Bailliere's Clin. Endocrin. Met.* 5(1):51-58. Disregulation of the hypothalamic-pituitary-adrenal (HPA) axis, which regulates physiological responses to stress, is correlated with atypical depression. The hypothalamus releases corticotrophic-releasing hormone (CRH) in response to stress, which in turn stimulates the anterior
25 —pituitary to secrete adrenocorticotrophic-releasing hormone (ACTH). ACTH stimulates the adrenal cortex to release cortisol which then signals the hypothalamus to regulate CRH production. In atypical depression, the hypothalamus secretes abnormally low levels of CRH, which in turn causes abnormally low activity in the HPA axis.

30 Dysthymia is another affective and mood disorder that is characterized by chronic despondency and loss of energy and interest. Additionally, an individual suffering from

dysthymia can experience hypophagia or hyperphagia, insomnia or hypersomnia, and lack of ability to concentrate. Dysthymia is often associated with higher than normal CRH levels, resulting in hyperactivity of the HPA axis; however, in individuals that tend to be overweight (i.e., have a higher body mass index (BMI) than normal), the CRH levels in
5 the hypothalamus can be lower in normal.

The association of leptin with both regulation of body weight and with affective disorders suggests that therapeutic strategies including leptin may offer new avenues for the treatment of a variety of disorders involving hypothalamic regulation (or dysregulation). The use of leptin to treat obesity in mice, however, requires very high,
10 non-physiological doses. Thus, leptin alone has not been found to be a particularly useful anti-obesity agent. Similar problems are expected with the use of leptin to treat affective disorders.

Typically, affective and mood disorders are treated with a variety of anti-depressant drugs. Such drugs have not proven to adequately or completely treat the
15 disorders, however, and in some cases, such drugs are lethal when acute overdosage occurs and can cause morbidity even under a physicians supervision. The frequency and severity with which affective and mood disorders occur in the general population emphasize the need for continued development of compounds and treatments to alleviate or prevent some or all of the symptoms associated with such conditions. Therefore, there
20 remains a need in the art for a simple, safe and effective method for the treatment of affective and mood disorders and conditions related to such disorders such as undesirable or health-compromising body weight.

By applying a POMC compound as described herein peripherally, when the naturally occurring form of such compound is normally produced centrally, peripheral
25 effects are stimulated while central nervous system effects can be controlled as desired, depending on the severity of the condition in a particular patient and the desired end result of the treatment. The method of the present invention will prevent patients from relying on psycho-active drugs. For example a depressed patient gaining weight may become dependent on appetite suppressants. The present invention provides a solution to this
30 problem.

In the practice of this embodiment of the present invention, it is useful, although not essential, to prepare therapeutic compositions (i.e., pharmaceutical formulations) comprising an effective amount of at least one POMC compound according to the present invention, either alone or in combination with one or more other anti-depressant and/or body weight regulating formulations or compounds as previously described herein (i.e., leptin). Such compositions, preferably in the form of a pharmaceutically acceptable salt and/or complexed with another suitable carrier (described below), can be formulated for any route of administration, including, but not limited to, parenteral administration and transdermal administration. In a preferred embodiment of the present invention, a therapeutic composition comprising a POMC compound, alone or in combination with one or more additional anti-depressant and/or body weight regulating compounds, is formulated to be administered in a manner which extends the time the composition remains in the bloodstream of an animal. As such, a therapeutic composition of the present invention typically includes a pharmaceutically acceptable carrier, and preferably, one which is capable of delivering the composition of the present invention to the peripheral circulation of the animal, and in some cases, is capable of prolonging the action of the composition in the bloodstream of the animal.

The effectiveness of dose parameters of a therapeutic composition of the present invention when used to control affective and mood disorders can be determined by assessing response rates. Such response rates refer to the percentage of treated patients in a population of patients that respond with either partial or complete improvement in the disorder, in a partial or complete loss of excess weight, or a reduction in the rate of weight gain, or alternatively, to a partial or complete gain of lost weight or a reduction in the rate of weight loss, to a level which is considered by those of skill in the art to be sufficient to address the needs of the particular patient and/or not present health risks to the patient.

— Response can be determined by, for example, measuring energy, mood, sleeping patterns, and/or weight loss or gain over time and/or measuring changes in levels of hormones and other biological indicators of the disorder in the animal, such as leptin.

Yet another embodiment of the present invention relates to a method to treat a reproductive disorder in an animal. Such a method includes the steps of administering to the periphery of an animal at risk for or suffering from a reproductive disorder a

therapeutic composition comprising a POMC compound. The POMC compound is administered in an amount effective to prevent and/or ameliorate the disorder, and/or to measurably regulate body weight in the animal, whereby administration of the compound to the central nervous system of the animal is minimized. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

In the original report of the *ob* mutation (Ingalls et al., 1950, *J. Hered.* 41:317-318), it was recognized that male and female homozygous *ob/ob* mice are sterile. Moreover, it was noted that *ob/ob* females are always sterile, and that *ob/ob* males can become fertile if maintained on a restricted diet (Lane et al., 1954, *J. Hered.* 45:56-58). Hummel et al. taught that the ovaries of *ob/ob* females are capable of producing viable eggs when transplanted into lean female recipients (Hummel et al., 1957, *Anat. Rec.* 128:569). Other research showed that early sexual development is normal in these mice, but ovulation never follows and the mice remain prepuberal indefinitely. FSH, LH and testosterone levels are reduced in *ob/ob* females (Swerdloff et al., 1976, *Endocrinology* 98:1359-1364), demonstrating the absence of a functional feedback from the hypothalamic-pituitary axis. Hypofunction of the pituitary gland in the female *ob/ob* mouse was demonstrated by showing that *in vivo* uterine weights of the mice did not significantly change after bilateral ovariectomy (Runner et al., 1954, *Genetics* 39:990-991; Drasher et al., 1955, *J. Heredity* 46:209-212) but did, however, respond to exogenous estrogen. Pituitary extracts administered to *ob/ob* females induced ovulation and conception, but no implantation (Runner, 1954, *Rec. Genet. Soc. Am.* 23:63-64) which was achieved following treatment with gonadotropic hormones (Runner et al., 1954, *J. Heredity* 45:51-55). Furthermore, the administration of high doses of progesterone maintained pregnancy for 19 days p.c., but did not enable the mothers to deliver the fetuses except after administration of relaxin which stimulated parturition and lactation (Smithberg et al., 1956, *J. Exp. Zool.* 133:441-458; Smithberg et al., 1957, *J. Heredity* 48:97-100). The above findings demonstrated that the sterility of the *ob/ob* female is caused by an insufficiency of hormones at the hypothalamic-pituitary level rather than physical hindrance of copulatory activity by excess adipose tissue.

While a majority of the prior art methods to treat reproductive disorders have involved the use of hormones, diet, or other compounds such as leptin (See U.S. Patent No. 5,866,547, *ibid.*), which are primarily directed to the regulation the central nervous system, the present invention is directed to the use of compounds which regulate the
5 *peripheral* pathways of energy homeostasis to treat reproductive disorders and conditions related thereto, including dysregulation of body weight. Such a method comprises administering to an animal that is at risk for or has reproductive dysfunction and/or a detrimental condition related thereto a therapeutic composition that regulates *the peripheral* melanocortinerbic pathway and/or the leptinerbic pathway of energy
10 homeostasis. Such a therapeutic composition may also regulate the central melanocortinerbic pathway of energy homeostasis. The compound and method of the present invention are believed to represent a new approach for the treatment of reproductive disorders which are expected to have particular advantages for alleviating, eliminating or preventing undesirable symptoms associated with such disorders, such as
15 excess or insufficient body weight.

Without being bound by theory, the present inventors believe that the regulation of other biological activities associated with body weight regulation, including hypothalamic-pituitary-adrenal axis activity suggests that the administration of such peptides and analogs thereof to a patient may affect both body weight regulation and the
20 other biological activities associated therewith (e.g., reproductive function).

As used herein, a reproductive disorder refers to any disorder characterized by hormonal deficiency which negatively affects the initiation of puberty, ovulation, conception, maintenance of pregnancy and/or delivery of offspring, such deficient hormone typically being one or more hypothalamic, pituitary or gonadal hormones.
25 Individuals having a reproductive disorder can include infertile and/or amenorrheic females, and particularly, females-incapable-of-or-having-a-reduced ability-to-ovulate, conceive, maintain pregnancy, lactate, and/or deliver a full-term offspring. Similarly, male individuals having a reproductive disorder can be characterized by an inability or reduced ability to impregnate females or enter puberty. According to the present invention, "to
30 treat" a disorder such as a reproductive disorder can also mean "to prevent" the disorder in a patient. Preferably, the disorder, or the potential for developing the disorder, is

reduced, optimally, to an extent that the patient no longer suffers from or does not develop the disorder (i.e., initiates or accelerates puberty, improves their ability to maintain pregnancy, etc.), or the discomfort and/or altered functions and detrimental conditions associated with such disorder (e.g., inability to ovulate, excessive accumulation of fat stores in adipose tissue, etc.).

In accordance with the present invention, a suitable or effective single dose size is a dose that is capable of causing a measurable change in the symptoms associated with the reproductive disorder (e.g., a decrease in body weight) of a patient when administered one or more times over a suitable time period. A suitable or effective single dose size can also be a dose that is capable of causing a measurable change in the symptom of the reproductive disorder in a patient as compared to the level of the symptom established prior to initiation of the treatment, when administered one or more times over a suitable time period. In addition, a suitable or effective single dose size is a dose that is capable of preventing or effecting a measurable improvement in a condition in the patient that is associated with or caused by the reproductive disorder. Such a condition includes, but is not limited to, ovulation, conception, pregnancy maintenance, lactation, delivery of a full term offspring, onset of menstruation, etc.. Doses can vary depending upon the condition of the patient being treated, including the apparent cause of the reproductive disorder and/or any other related or non-related health factors experienced by a particular patient.

In particular, the effectiveness of dose parameters of a therapeutic composition of the present invention when used to control reproductive disorders can be determined by assessing response rates. Such response rates refer to the percentage of treated patients in a population of patients that respond with either partial or complete improvement in the disorder, in a partial or complete loss of excess weight, or a reduction in the rate of weight gain, or alternatively, to a partial or complete gain of lost weight or a reduction in the rate of weight loss, to a level which is considered by those of skill in the art to be sufficient to address the needs of the particular patient and/or not present health risks to the patient. Response can be determined by, for example, onset of menstruation, ability to conceive and/or maintain a pregnancy, and/or weight loss or gain over time and/or measuring

changes in levels of hormones and other biological indicators of the disorder in the animal, such as leptin.

In accordance with the present invention, a suitable or effective single dose size is a dose that is capable of causing a measurable change in the symptoms associated with the reproductive disorder (e.g., a decrease in body weight) of a patient when administered one or more times over a suitable time period. A suitable or effective single dose size can also be a dose that is capable of causing a measurable change in the symptom of the reproductive disorder in a patient as compared to the level of the symptom established prior to initiation of the treatment, when administered one or more times over a suitable time period. In addition, a suitable or effective single dose size is a dose that is capable of preventing or effecting a measurable improvement in a condition in the patient that is associated with or caused by the reproductive disorder. Such a condition includes, but is not limited to, ovulation, conception, pregnancy maintenance, lactation, delivery of a full term offspring, onset of menstruation, etc.. Doses can vary depending upon the condition of the patient being treated, including the apparent cause of the reproductive disorder and/or any other related or non-related health factors experienced by a particular patient.

In one embodiment of the present invention, POMC compounds, alone or in combination with leptin, are used to *enhance* the effects of a conventional treatment for reproductive disorders, such as hormone therapy.

Yet another embodiment of the present invention relates to a method and compound for controlling excess or insufficient body weight (i.e., decreasing body weight, reducing weight gain, increasing body weight, or reducing weight loss) that is a side effect of using another pharmaceutical compound. Such a method comprises administering to the periphery of an animal that is at risk for or has undesired body weight due to a side effect of a pharmaceutical compound a therapeutic composition that regulates *the peripheral* melanocortinerbic pathway and/or the leptinerbic pathway of energy homeostasis. The composition comprises a POMC compound in an amount effective to measurably decrease body weight or weight gain in said animal, whereby administration of said compound minimizes delivery of said compound to the central nervous system of

said animal. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

In a preferred embodiment, the present invention relates to reducing body weight and/or reducing weight gain in an animal, and more particularly, to treating or ameliorating obesity in patients at risk for or suffering from obesity which is caused as a side effect of using a pharmaceutical. Conditions for which pharmaceuticals are prescribed which can cause undesired body weight include, but are not limited to, epilepsy, attention deficit hyperactivity disorder (ADHD), depression, bipolar disorder, and migraine. Pharmaceuticals (i.e., drugs) which have a well documented side effect of undesired weight gain or loss include, but are not limited to valproic acid (i.e., Depakote), lithium, tricyclic antidepressants (e.g., amitriptyline, nortriptyline or desipramine), and selective serotonin reuptake inhibitors (SSRI) such as fluoxetine (i.e., Prozac).

Yet another embodiment of the present invention relates to a food composition for use with humans or other animals which regulates body weight or the rate of body weight gain or loss. The food composition comprises a proopiomelanocortin (POMC) compound (i.e., the food additive) which can include, but is not limited to: POMC peptides or fragments, homologues, peptide mimetics, non-peptide mimetics, fusion proteins or pharmaceutically acceptable salts thereof. The POMC compound of the present invention can be administered with or without additional compounds, including other body weight regulating compounds, such as leptin, although in the case of compounds such as leptin, the leptin must be protected from the gastrointestinal tract by any suitable means, or be administered by a different route. In a preferred embodiment, the food composition ameliorates obesity in obese animals, but does not significantly diminish weight in normal animals. Therefore, including POMC proteins in foodstuffs is ameliorative to obese individuals who consume such foodstuffs, but does not significantly affect normal individuals who may not have the genetic propensities leading to obese conditions. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

According to the present invention a food composition useful herein is any food stuff (i.e., consumable, edible material) which can contain a food additive including a POMC compound as described herein, and which is preferably capable of protecting the

POMC compound within the gastrointestinal tract and allowing at least a portion of the POMC compound to enter the blood stream. In the practice of the present invention, it is useful, although not essential, to prepare food compositions comprising an effective amount of at least one POMC compound according to the present invention, either alone
5 or in combination with one or more other body weight regulating formulations or compounds as previously described herein (i.e., leptin). Such compositions, preferably in the form of a pharmaceutically acceptable salt and/or complexed with another suitable carrier (described below), are formulated for use in a food composition (i.e., non-toxic, suitable for use as a food additive). In a preferred embodiment of the present invention,
10 a food composition comprising a POMC compound, alone or in combination with one or more additional body weight regulating compounds, is formulated to protect the compound long enough for the compound to enter the bloodstream, and to extend the time the composition remains in the bloodstream of an animal. As such, a food composition of the present invention typically includes an acceptable carrier, and
15 preferably, one which is capable of protecting the compound in the gastrointestinal tract and/or prolonging the action of the composition in the bloodstream of the animal.

For example, food compositions of the present invention can be formulated in an excipient that the animal to be treated can tolerate. In one embodiment, such an excipient is suitable for use in a composition which is to be administered for delivery to the
20 peripheral circulation. Examples of such excipients include water, saline, phosphate buffered solutions and other aqueous, physiologically balanced, salt solutions. Nonaqueous vehicles, such as fixed oils, sesame oil, ethyl oleate, or triglycerides may also be used.

Yet another embodiment of the present invention relates to a method for
25 increasing body weight and/or mass and/or reducing the rate of weight and/or mass loss in a patient, as a part of a treatment program for eating disorders such as anorexia or bulimia. The method includes the step of administering to an animal a therapeutic composition comprising a proopiomelanocortin (POMC) antagonist compound, wherein the POMC compound is administered to the periphery of the animal in an amount effective
30 to measurably increase body weight or reduce body weight loss in the animal, whereby administration of the compound minimizes delivery of the compound to the central

nervous system of the animal. Various aspects of such a method, including compounds, administration protocols, and desired effects, have been previously described herein.

5 The rise in bulimia and anorexia in the past few decades is alarming, and illustrates the disturbing emphasis on ideal body size and shape regardless of the severe health consequences. The regulation of body weight is a major health concern throughout the world, and particularly in the United States, contributing to morbidity and mortality. For certain individuals, however, regulation of body weight is driven by psychological conditions and an overwhelming desire to be thin. While obesity is a metabolic disorder characterized by excessive accumulation of fat stores in adipose tissue, and is caused by
10 a complex interplay of genetics, environment and culture, eating disorders resulting in unhealthy weight loss are typically psychological problems associated with deeper issues, including depression or lack of self esteem, which drive an individual to participate in unhealthy eating habits. It is well known that a regimen of diet and exercise leading to weight loss is the best approach for reaching a healthy body weight, but unfortunately,
15 such regimens are grossly abused by the individual with an eating disorder.

In addition to the obvious health risks associated with being underweight, the tangential detrimental effects of such conditions are equally troublesome. Conditions related to or affected by low body weight can include heart failure, susceptibility to infectious disease as a result of immune system weakness, and depression. For individuals
20 suffering from an eating disorder, the goal of therapy, in addition to treating the psychological problem, is to increase the body weight of the patient.

The method of the present invention is useful for treating any eating disorder that is characterized by or associated with unhealthy body weight or body mass loss. Such conditions, include, but are not limited to anorexia and bulimia. The present invention
25 is not necessarily intended to be a "cure" for such conditions, but rather, is intended to be used in conjunction with appropriate conventional therapy for eating disorders (e.g., psychotherapy) which addresses the root of the condition itself. More particularly, the present invention relates to a composition and method for increasing body weight which may have certain advantages as discussed below.

30 The method of the present invention is useful for treating any animal for the purposes of increasing body weight and/or mass and/or decreasing the rate of weight

and/or mass loss. In particular, the method of the present invention is useful for treating any animal that has an eating disorder including, but not limited to, anorexia and bulimia. The phrase, "to treat" a condition such as anorexia in a patient refers to reducing, ameliorating or preventing the condition in a patient that suffers from the condition or is at risk of acquiring the condition. Therefore, in one embodiment of the present invention, "to treat" a disorder can also mean "to prevent" the disorder in a patient. Preferably, the condition, or the potential for developing the condition, is reduced, optimally, to an extent that the patient no longer suffers from the condition or begins to accumulate fat stores in adipose tissue and/or body cell mass, or to decrease the discomfort and/or altered functions and detrimental conditions associated with the loss of fat stores and body cell mass. More particularly, "to treat" a condition associated with excessively low weight and/or mass loss includes the administration of POMC antagonist compounds as disclosed herein to prevent the onset of the symptoms or complications of such a condition, to alleviate the symptoms or complications, or to eliminate the condition. In the case of an eating disorder, such treatment is typically only a small portion of an overall therapy which includes a significant amount of psychotherapy.

According to the present invention, an effective administration protocol (i.e., administering a POMC antagonist compound or a therapeutic composition comprising such a compound in an effective manner) comprises suitable dose parameters and modes of administration that result in regulation of body weight and/or mass (i.e., increase in body weight and/or mass or decrease in rate of weight and/or mass loss) in the animal when administered one or more times over a suitable time period. Effective dose parameters can be determined using methods standard in the art for a particular animal and condition. Such methods include, for example, determination of survival rates, side effects (i.e., toxicity) and other health factors associated with, or in addition to the amount of body weight and/or mass gain desired in the animal. In particular, the effectiveness of dose parameters of a therapeutic composition of the present invention when used to control body weight and/or mass can be determined by assessing response rates. Such response rates refer to the percentage of treated patients in a population of patients that respond with either partial or complete gain of lost weight and/or mass (as compared to a previous, healthy or normal weight and/or mass for the patient prior to the onset of the

disorder) or a reduction in the rate of weight and/or mass loss, to a level which is considered by those of skill in the art to be sufficient to address the needs of the particular patient and/or not present health risks to the patient. Response can be determined by, for example, measuring weight and/or mass gain over time and/or measuring changes in levels of hormones and other biological indicators of weight loss and metabolic control in the animal, for example, leptin.

Another embodiment of the present invention generally relates to a non-human animal model for studying and developing protocols for modifying the peripheral as well as the central melanocortineric pathways controlling body weight. In particular, this aspect of the present invention relates to a genetically modified non-human animal which has a genetic modification that results in a reduction, and preferably absence, of proopiomelanocortin (POMC) peptide action in the animal, and the use of such an animal for studying and developing protocols for controlling body weight and health-compromising conditions related thereto.

More particularly, the present inventors disclose herein the development and characterization of a *Pomc* mutant mouse which is a model of obesity, and which can be used to study and develop protocols for the treatment of a variety of conditions related to undesirable and/or medically unhealthy body weight. The *Pomc* mutant mouse was engineered to carry an autosomal recessive null allele of the *Pomc* gene (i.e., *pomc*). This mouse lacks all of the peptide hormones encoded by the *Pomc* locus. The present inventors have discovered that mice lacking the POMC peptides have obesity, a defect in adrenal development, and altered pigmentation. This phenotype is similar to the recently identified human *Pomc* mutants (Krude, et al., 1998, *Nat Genet* 19, 155-7). In addition to a dysregulation of fat metabolism, the POMC-deficient mice showed increased food intake.

When the inventors treated the mutant mice peripherally with a stable α -MSH agonist, these mice lost over 40% of their excess weight after two weeks, whereas wildtype non-obese mice did not lose significant weight. The present inventors have shown that the weight changes in POMC null mice are not simply regulated through feeding behavior, but rather through both central and peripheral actions of melanocortins. Based on *in vivo* experiments described herein, the present inventors have shown MSH

to be an adiposity regulating hormone. Most importantly, peripheral treatment of *pomc/pomc* mutants with an MSH mimetic ameliorated obesity, but did not significantly diminish weight in normal mice. Consequently, these results indicate that certain subpopulations of obese patients will be particularly amenable to treatment with MSH and homologues and mimetics thereof, although the present invention indicates that the use of POMC compounds to treat any patient with undesired body weight is feasible. Pharmacological agents which are biologically active and mimic the activity of MSH are therefore useful for treating obese patients, particularly those with abnormal levels of circulating MSH. The present inventors are the first to appreciate that the POMC peptides have both a central and peripheral effect on feeding behavior and in body weight regulation.

Furthermore, the present inventors have demonstrated that the POMC null mutant mouse is a model for studying the human POMC null syndrome. In addition to having a mouse model for the human POMC deficiency, the *Pomc* mutant mouse is a valuable addition to the growing number of murine obesity models, aiding in the dissection of the mechanisms of energy homeostasis, centrally and peripherally, as well as in exploring therapeutic regimens for the human POMC deficient patients and possibly for other, multigenic-multifactorial forms of human obesity. The anti-obesity effects of MSH indicate a therapeutic use in POMC-deficient as well as other forms of obesity.

One embodiment of the present invention relates to a genetically modified non-human animal useful for studying peripheral and central pathways of energy homeostasis. The genetically modified non-human animal comprises a genetic modification within at least one allele of its *Pomc* locus, wherein the genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in the animal (e.g., a heterozygous mutant animal). In one embodiment, the genetic modification includes, but is not limited to, a deletion, an insertion, a substitution and/or an inversion of nucleotides in the *Pomc* locus which result in a reduction in POMC peptide action in the animal. The genetic modification can be a modification including or within exon 3 of the *Pomc* locus which results in a reduction in POMC peptide action, and/or a modification in a region of the *Pomc* locus other than exon 3 which results in a reduction in POMC peptide action (e.g., exon 1, exon 2 and/or a regulatory region of the *Pomc* locus). In a preferred embodiment,

the genetic modification is a deletion of a nucleic acid sequence within at least one allele of the *Pomc* locus, wherein the deletion results in an reduction of expression of POMC peptides by said animal. In another embodiment, the animal comprises a genetic modification within two alleles (i.e., both alleles) of the *Pomc* locus, wherein the genetic modification results in an absence of POMC peptide action in the animal (e.g., a homozygous mutant animal). Preferably, the genetic modification is a deletion of a nucleic acid sequence within both alleles of the *Pomc* locus, wherein the deletion results in an absence of expression of POMC peptides by the animal. POMC peptides have been described in detail previously herein.

As used herein, reference to POMC peptides is intended to refer generically to any one or more of the POMC peptides encoded by the *Pomc* locus. If reference to a specific POMC peptide, such as MSH, is intended, the name of the specific peptide will be used. The nucleic acid and amino acid sequences for the naturally occurring POMC peptides in a large variety of animals (i.e., human, mouse, rat, rabbit, bovine, ovine, macaque, amphibian, etc.) are known in the art. Such sequences can be found, for example, in a protein or nucleic acid database such as GenBank. GenBank accession numbers for such POMC peptide (i.e., amino acid) sequences include, but are not limited to: Accession Nos. NP_000930 or CAA24754 (*Homo sapiens*); Accession No. P06297 (rabbit); Accession No. P01194 (rat); Accession No. P01193 (mouse); Accession No. P01191 (sheep); and, Accession No. P01190 (bovine). GenBank accession numbers for such *Pomc* nucleic acid sequences include, but are not limited to: Accession No. NM_000939 (*Homo sapiens*); Accession No. AH005319 (mouse); Accession Nos. J00016, J00019, J00021 (bovine); Accession No. S73519 (swine); S57982 (ovine); and Accession No. AH002232 (rat). Exons 1, 2 and 3 for the mouse *Pomc* locus are identified as GenBank Accession Nos. J00610, J00611 and J00612, respectively.

As used herein, a non-human animal suitable for genetic modification according to the present invention is any non-human animal for which the *Pomc* locus can be manipulated, including non-human members of the Vertebrate class, Mammalia, such as non-human primates and rodents. Preferably, such a non-human animal is a rodent, and more preferably, a mouse. Genetically modified mice which have either a reduction or an absence of POMC peptide expression are described in detail in the Examples section.

According to the present invention, a "genetically modified" animal, such as any of the preferred non-human animals described herein, has a genome which is modified (i.e., mutated or changed) from its normal (i.e., wild-type or naturally occurring) form such that the desired result is achieved (e.g., a reduction in the action of POMC peptides).

5 Genetic modification of an animal is typically accomplished using molecular genetic and cellular techniques, including manipulation of embryonic cells and DNA (e.g., DNA comprising the *Pomc* locus). Such techniques are generally disclosed for mice, for example, in "Manipulating the Mouse Embryo" (Hogan et al., Cold Spring Harbor Laboratory Press, 1994, incorporated herein by reference in its entirety). Additionally,
10 techniques for genetic modification of a mouse through molecular technology are described in detail in the Examples section.

A genetically modified non-human animal can include a non-human animal in which nucleic acid molecules have been modified (i.e., mutated; e.g., by insertion, deletion, substitution, and/or inversion of nucleotides), in such a manner that such
15 modifications provide the desired effect within the animal (i.e., reduction in POMC peptide action). As used herein, genetic modifications which result in a reduction in gene expression, in the function of the gene, or in the function of the gene product (i.e., the protein encoded by the gene) can be referred to as inactivation (complete or partial), deletion, interruption, blockage or down-regulation of a gene. For example, a genetic
20 modification in a gene which results in a decrease in the function of the protein encoded by such gene, can be the result of: a partial or complete deletion of the gene or of an exon within the gene (i.e., the gene does not exist, and therefore the protein can not be produced); a mutation (e.g., a deletion, substitution, insertion and/or inversion) in the gene which results in incomplete or no translation of the protein (e.g., a mutation which causes
25 a frame shift so that the correct protein is not expressed, a mutation in one or more exons of the gene so that the protein or at least a portion of the protein is not expressed, or a mutation in a regulatory region so that the protein is not expressed or has reduced expression); or a mutation in the gene which decreases or abolishes the natural function of the protein (e.g., a protein is expressed which has decreased or no biological activity
30 or action).

According to the present invention, a genetic modification of a non-human animal results in a reduction (i.e., decrease, inhibition, down-regulation) of the action of POMC peptides. Such a genetic modification includes any type of modification to a genome of the animal, particularly including modifications made at the embryonic stage of development of the animal (or in the ancestor of the animal). Such modifications are described above. According to the present invention, reference to reducing "the action" (or activity) of POMC peptides refers to any genetic modification in the non-human animal which results in decreased functionality of one or more of the POMC peptides, including: reduced biological activity of the peptides (e.g., reduced *in vivo* hormonal activity); inhibition or degradation of the peptides (i.e., the peptides are expressed, but are inhibited or degraded as a result of the genetic modification); and reduced, or abolished, expression of the peptides (i.e., by complete or partial gene deletion, substitution, insertion, etc.). For example, the action of POMC peptides can be decreased by blocking or reducing the production of the peptides, "knocking out" the gene or a portion of the gene encoding the peptides, reducing peptide activity, or inhibiting the activity of the peptides.

In one embodiment of the present invention, a non-human animal of the present invention is genetically modified by modification of a nucleic acid sequence within one (i.e., heterozygous) or both (i.e., homozygous) alleles of the *Pomc* locus, wherein such modification can include, but is not limited to, a deletion, an insertion, a substitution and/or an inversion within the one or more nucleotides in the *Pomc* locus. In one embodiment, the genetic modification is in a nucleic acid sequence that includes exon 3 of the *Pomc* locus, such modification resulting in a decrease in POMC peptide action in the animal. In another embodiment, the genetic modification is in a region of the *Pomc* locus other than exon 3, whereby the modification results in a decrease in POMC peptide action in the animal. Such other regions include exon 1, exon 2 or a regulatory region of the *Pomc* locus. According to the present invention, a regulatory region of a gene includes any regulatory sequences that control the expression of nucleic acid molecules, including promoters, enhancers, transcription termination sequences, sequences that regulate translation, and origins of replication.

In a preferred embodiment of the present invention, a non-human animal of the present invention is genetically modified by deletion of a nucleic acid sequence within one

or both alleles of the *Pomc* locus, wherein the deletion results in a reduction or absence, respectively, of expression of POMC peptides by the animal. In one embodiment, such a genetic modification is a deletion of a nucleic acid sequence comprising exon 3 of *Pomc*. In another embodiment, the genetic modification is a deletion of exon 3 of *Pomc*. In yet another embodiment, the genetic modification is a deletion of a portion of exon 3 of *Pomc* sufficient to reduce or prevent expression of POMC peptides by at least one allele and more preferably, by both alleles, of the *Pomc* locus of the animal.

In one embodiment of the present invention, the genetically modified non-human animal is a mouse, also referred to herein as a POMC homozygous mutant mouse. In this embodiment, the genetic modification is preferably a deletion from the genome of a nucleic acid sequence comprising SEQ ID NO:7, although any genetic modification of the *Pomc* locus as described above is encompassed by the present invention. SEQ ID NO:7 represents exon 3 of the mouse (i.e., *Mus musculus*) *Pomc* locus and can be located in the GenBank database as GenBank Accession No. J00612. SEQ ID NO:7 encodes an amino acid sequence represented herein as SEQ ID NO:8. Preferably, the genetic modification in the mouse is a deletion from the genome of exon 3 of *Pomc* (SEQ ID NO:7).

The genetically modified non-human animal of the present invention can be characterized by several phenotypes which result from the reduction or absence in POMC peptide action in the animal. Such phenotypic characteristics include: obesity, a defect in adrenal development, and/or altered pigmentation. In addition, the present inventors have discovered that such a genetically modified non-human animal has measurably increased serum leptin levels as compared to a wild-type sibling of the animal. Other phenotypic characteristics associated with the genetic modification include: an increased food uptake as compared to a wild-type sibling of the animal and/or measurably reduced serum levels of a hormone selected from the group of corticosterone, aldosterone and epinephrine as compared to a wild-type sibling of the animal.

As used herein, a wild-type sibling, or wild-type littermate, is an animal which is born to the same or genetically identical parents as a genetically modified animal described herein, and preferably, is born in the same litter as a genetically modified animal described herein, but which did not inherit a genetically modified allele at the *Pomc* locus. Such an

animal is essentially a normal animal and is useful as an age-matched control for the methods described herein.

According to the present invention, a non-human animal can be genetically modified by any method which results in the desired effect (i.e., reduction in POMC peptide action in the animal). Such methods are typically molecular techniques, and include, but are not limited to, any deletion of at least a portion of the *Pomc* locus in the animal, any insertion of a non-*Pomc* sequence into at least a portion of the *Pomc* locus in the animal, or any substitution of at least a portion of the *Pomc* locus in the animal with any non-*Pomc* sequence or mutated *Pomc* sequence, sufficient to reduce POMC peptide action in the animal. For example, a *Pomc* locus in the genome of an animal (or an embryonic cell) can be genetically modified by inserting into at least one allele of the *Pomc* locus of the animal or cell an isolated nucleic acid molecule which encodes at least a section of the *Pomc* gene. At least a portion of this isolated section of the *Pomc* gene is mutated (i.e., by deletion of the portion, substitution of the portion with another, non-*Pomc* sequence, or insertion of a non-*Pomc* sequence into the section of *Pomc*), such that when the isolated nucleic acid molecule is inserted into the endogenous *Pomc* locus of the animal or cell, the animal or cell will have a reduction or elimination in the action of POMC peptides as described above. As another example, in one embodiment of the invention, a genetically modified mouse is produced by inserting into the genome of an embryonic stem (ES) cell an isolated nucleic acid molecule (e.g., a targeting vector) having an isolated nucleic acid sequence encoding the murine *Pomc* gene. In this isolated nucleic acid sequence, exon 3 of the murine *Pomc* gene has been deleted and replaced with a non-*Pomc* nucleic acid sequence (e.g., a marker sequence, such as a neomycin cassette). The isolated nucleic acid molecule is preferably designed such that when the molecule is injected into embryonic stem (ES) cells, the isolated nucleic acid molecule will integrate into the genome of the cells, preferably at the endogenous *Pomc* locus (i.e., targeted integration).

Techniques for achieving targeted integration of an isolated nucleic acid molecule into a genome are well known in the art and are described, for example in "Manipulating the Mouse Embryo", *supra*. For example, the isolated nucleic acid molecule can be engineered into a targeting vector which is designed to integrate into a host genome.

According to the present invention, a targeting vector is defined as a nucleic acid molecule which has the following three features: (1) genomic sequence from the target locus in the host genome to stimulate homologous recombination at that locus; (2) a desired genetic modification within the genomic sequence from the target locus sufficient to obtain the desired phenotype; and (3) a selectable marker (e.g., an antibiotic resistance cassette, such as G418, neomycin, or hygromycin resistance cassettes). Such targeting vectors are well known in the art. Following introduction of the isolated nucleic acid molecule of the targeting vector into the ES cells, ES cells which homologously integrate the isolated nucleic acid molecule are injected into mouse blastocysts and chimeric mice are produced. These mice are then bred onto the desired mouse background to detect those which transmit the mutated gene through the germ line. Heterozygous offspring of germline transmitting lines can then be mated to produce homozygous progeny.

Mice which carry one or more mutated *Pomc* alleles can be identified using any suitable method for evaluating DNA. For example, genotypes can be analyzed by PCR and confirmed by Southern blot analysis as described (Sambrook et al., 1988, Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Press, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York or Current Protocols in Molecular Biology (1989) and supplements).

According to the present invention, an isolated nucleic acid molecule suitable for use in the present invention (e.g., suitable for use in a targeting vector according to the invention) is typically produced using recombinant DNA technology (e.g., polymerase chain reaction (PCR) amplification, cloning) or chemical synthesis. DNA comprising the desired nucleic acid sequence (e.g., the *Pomc* locus, modified or unmodified) may be created, for example, by using polymerase chain reaction (PCR) techniques or other cloning techniques. The template can be a genomic or cDNA library isolated from central nervous system or pituitary tissue. Such methodologies are well known in the art (Sambrook et al., *supra*).

One embodiment of the present invention relates to a method for studying the molecular and biochemical events associated with body weight gain and loss, and particularly, with such events that are associated with obesity. More particularly, such a method includes the steps of: (a) harvesting cells, tissues or body fluids from a genetically

modified non-human animal of the present invention; and, (b) comparing the cells, tissues or body fluids from the genetically modified non-human animal to cells, tissues or body fluids from a wild-type sibling of the genetically modified non-human animal. The step of harvesting is performed using any of the well known methods of harvesting cells, tissues and/or body fluids from an animal, and depend on the tissues to be studied and the status of the experiment to be performed. For example, cells can be harvested by biopsy, dissection, or lavage; tissues can be harvested by surgery, biopsy or dissection; and body fluids can be harvested by withdrawal, swiping, or lavage.

The step of comparing is performed by an assay that is suitable for the tissue to be evaluated and the goal of the experiment. For example, suitable assays which might be performed on the cells, tissues, and/or body fluids of a genetically modified non-human animal of the present invention include, but are not limited to: morphological examination of the cells, tissues or body fluids; histological examination of the cells, tissues or body fluids; evaluation of POMC peptide biological activity in the animal; evaluation of free fatty acid metabolism in the animal; evaluation of lipolysis and fatty acid sequestration in the animal; evaluation of weight gain or loss in the animal; evaluation of hormone levels in the animal; evaluation of blood biochemistry in the animal. A variety of such assays are well known in the art.

Another embodiment of the present invention relates to a method to identify POMC compounds, and particularly, homologues and mimetics, for use in regulating peripheral and central pathways of energy homeostasis. Such a method includes screening a compound to be evaluated for its ability to stimulate lipolysis and/or to inhibit fatty acid uptake by adipocytes, and in particular, to control body weight in a genetically modified non-human animal of the present invention. Such a method can be performed *in vitro* (e.g., by using cells, tissues or body fluids of the genetically modified animal as described above) or *in vivo* (e.g., by administering regulatory compounds to a genetically modified animal of the present invention and evaluating the effects of such compounds *in vivo*). Regulatory compounds identified by this method are useful for controlling body weight in an animal, and may have additional beneficial therapeutic effects on disorders and conditions related to excess body weight in an animal. In particular, the method of the present invention includes the steps of: (a) administering a compound to be evaluated to

a genetically modified non-human animal which comprises a genetic modification within two (both) alleles of its *Pomc* locus, wherein the genetic modification results in an absence of POMC peptide action in the animal; and, (b) evaluating physiological and pathological changes in the genetically modified non-human animal as compared to a non-human animal selected from the group of: (i) a second genetically modified non-human animal comprising a genetic modification within at least one allele of its *pomc1* locus, wherein the genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in the animal; and (ii) a third non-human animal having a genome comprising a wild-type *pomc1* locus at two (i.e., both) alleles.

As discussed previously herein, the present inventors have discovered that when the POMC homozygous mutant mice described herein were treated peripherally with a stable α -MSH agonist, these mice lost over 40% of their excess weight after two weeks, whereas wildtype non-obese mice did not lose significant weight. The present inventors have shown that the weight changes in *Pomc* mutant mice are not simply regulated through feeding behavior, but rather through both central and peripheral actions of melanocortins. Based on *in vivo* experiments described herein, the present inventors have shown MSH to be a peripherally acting, adiposity regulating hormone.

The first step of the method of the present invention includes the step of administering to the genetically modified non-human a regulatory compound to be evaluated. According to the present invention, suitable compounds to be evaluated for regulatory activity in the present method preferably include compounds which have an unknown regulatory activity or an undetermined level of regulator activity, at least with respect to the ability of such compounds to regulate body weight and/or biochemical or molecular events associated with regulation of body weight, as well as compounds which have a known ability to regulate body weight and or biochemical or molecular events associated with regulation of body weight and analogs of such known compounds. Particularly preferred putative regulatory compounds to test in the method of the present invention include any proopiomelanocortin (POMC) compounds, which preferably include a homologue of a POMC peptide, a peptide or non-peptide mimetic of a POMC peptide, a fusion protein including a POMC peptide, or a recombinant nucleic acid molecule encoding such a POMC peptide, fragment, homologue, peptide mimetic, or fusion protein

thereof. It is noted, however, that other non-POMC compounds can also be evaluated in the method of the present invention. One example of such a non-POMC compound is leptin. In a preferred embodiment, the POMC compound is a melanocyte stimulating hormone (MSH) compound. The method of the present invention is also useful for
5 evaluating the relative benefits of compounds which are believed or known by the present inventors to be capable of regulating body weight in an animal. Such compounds include several POMC compounds, including POMC peptides, fragments of such peptides, homologues of such peptides, and mimetics of such peptides. In the case of compounds which are believed or known to be regulators of body weight, the animal model of the
10 present invention is useful for comparing these compounds to each other or to putative regulatory compounds, and for addressing issues related to dosage, toxicity, and other factors associated with the administration of a compound to an animal.

In one embodiment of the present invention, POMC homologues and mimetics are evaluated for increased or decreased stability and/or increased or decreased biological
15 activity compared to an unmodified POMC peptide (i.e., a naturally occurring or prototype POMC peptide). As used herein, the biological activity or biological action of a protein (e.g., a peptide) refers to any function(s) exhibited or performed by a naturally occurring form of the protein as measured or observed *in vivo* (i.e., in the natural physiological environment of the protein in the organism) or *in vitro* (i.e., under laboratory
20 conditions, in tissue culture or cell free systems, for example). For example, a biological activity of a protein can include, but is not limited to, hormone activity, protein binding activity, receptor binding activity, calcium binding activity, protein translocation, or DNA binding activity. Modifications of a protein, such as in a homologue or mimetic, which result in a decrease in protein expression or a decrease in the activity of the protein, can
25 be referred to as inactivation (complete or partial), down-regulation, or decreased action of a protein. Similarly, modifications which result in an increase in protein expression or an increase in the activity of the protein, can be referred to as amplification, overproduction, activation, enhancement, up-regulation or increased action of a protein.

As discussed previously herein, in accordance with the present invention, increased
30 stability refers to the property of a POMC homologue or mimetic to have a longer half-life (i.e., have greater stability under physiological conditions, such as in serum), by being

more resistant, for example, to proteolytic degradation compared to proteins comprising unmodified POMC peptides, to higher or lower temperature, to more acidic or basic pH, to higher or lower salt concentrations, to oxidation and/or reduction, to deamidation, and to other forms of chemical degradation. Similarly, decreased stability refers to the property of a mimetic to be less resistant, for example, to such conditions.

Methods of administration of a compound, including dose, route of administration and other formulation of a compound or composition have been previously described herein for POMC compounds and apply to a putative regulatory compound to be evaluated in this method of the invention.

The second step in the method of the present invention includes evaluating physiological and pathological changes in the homozygous genetically modified non-human animal as compared to a heterozygous genetically modified non-human animal and/or a wild type animal. Such physiological and pathological changes include, but are not limited to, changes in body weight (i.e., increase or decrease), changes in body mass, changes in hair or skin pigmentation, changes in adrenal morphology and/or function, changes in circulating hormone levels (e.g., corticosterone, aldosterone, epinephrine), changes in serum leptin levels, changes in appetite, and any other measurable change in the physiology of the animal. Such changes can be evaluated by well known methods in the art, most of which are exemplified in the Examples section.

Yet another embodiment of the present invention relates to a method of producing a genetically modified non-human animal useful for studying peripheral and central pathways of energy homeostasis. Such a method includes the steps of: (a) introducing into an embryonic stem cell of a non-human animal a targeting vector comprising a *Pomc* locus containing a deletion of a nucleic acid sequence sufficient to result in a reduction in proopiomelanocortin (POMC) peptide action in the animal; and, (b) obtaining progeny having the deletion stably incorporated into their genome, wherein the deletion results in a reduction in expression of proopiomelanocortin (POMC) peptides by the animal. In one embodiment, this method additionally includes the step of obtaining progeny having the deletion stably incorporated into their genome, wherein the deletion results in an *absence* of expression of POMC peptides by the animal. This third step can be achieved, for example by mating the progeny of step (b) (i.e., heterozygous animals) with each other

to obtain the desired phenotype (i.e., homozygous animals). This method has been described in detail above and are exemplified in the Examples section.

Another embodiment of the present invention is a genetically modified mouse useful for studying peripheral and central pathways of energy homeostasis. The mouse is produced by a method comprising the steps of: (a) isolating from a source of murine genomic DNA a nucleic acid molecule comprising SEQ ID NO:7; (b) deleting a nucleic acid sequence comprising SEQ ID NO:7 from the nucleic acid molecule to form a genetically modified nucleic acid molecule; (c) inserting a selectable marker into the genetically modified nucleic acid molecule to create a targeting vector; (d) transfecting the targeting vector into embryonic stem cells; (e) selecting embryonic stem cells from step (d) which have incorporated the targeting vector by homologous recombination; (f) inserting the embryonic stem cells comprising the targeting vector into non-human animal blastocysts; and, (g) impregnating a female surrogate with the non-human animal blastocysts to produce the genetically modified mouse. Methods for practicing this method have been described in detail previously herein and are exemplified in the Examples section.

Various aspects of the present invention are illustrated in the following examples, which are provided for the purposes of illustration and are not intended to limit the scope of the present invention.

EXAMPLES

Example 1

The following example describes the production of the POMC null mutant mouse of the present invention and demonstrates that POMC peptides are associated with the regulation of body weight through both central and peripheral mechanisms.

To create a mutant mouse strain lacking all proopiomelanocortin (POMC) derived peptides, the present inventors designed a targeting vector in which the entire third exon (Notake et al., 1983, *FEBS Lett* 156:67-71; incorporated herein by reference in its entirety) is replaced by a neomycin resistance cassette. Briefly, EcoRI-digested 129/SvEv genomic DNA was cloned into lambda FixII (Stratagene). The resulting library was

screened with a 0.3 kb PCR fragment from exon 3 of the mouse *Pomc1* sequence, and a clone carrying a 9.5 kb fragment containing the mouse *Pomc1* locus was isolated. For the targeting vector the KpnI-PstI fragment containing the third exon was deleted. This removes all but the first 44 codons for amino acids after the translation start of the pre-protein, or all but the first 18 codons for amino acids of the POMC protein. Targeting vector (20 µg) was used to electroporate 10⁷ RW4 ES cells (Genome Systems). ES cells which homologously integrated the mutated allele were injected into C57BL/6 blastocysts as described (Hogan et al., "Manipulating the Embryo", Cold Spring Harbor Laboratory Press, 1994). Chimeric mice were mated to 129/SvEvTac females. Heterozygous offspring were mated to generate homozygous mutant mice. Genotypes were analyzed by PCR and confirmed by Southern blot analysis as described (Sambrook et al. *ibid.*).

Fig. 1A shows schematic diagrams and restriction maps of the mouse POMC locus, the targeting vector, and the predicted structure of the POMC locus after homologous recombination. The 0.4kb probe fragment hybridizes to a 9.5 kb EcoRI fragment in the wildtype allele, and to a 3.2kb fragment in the mutant allele (see also Fig. 1B). Restriction sites indicated are EcoRI (E), KpnI (K), and PstI (P). Fig. 1B shows Southern blot analyses of tail DNAs from F₂ littermates. The probe used was the 0.4 kb PstI-EcoRI fragment (see Fig. 1A). Fig. 1C shows an RIA analysis of serum ACTH levels in F₂ male littermates (measurements in triplicates, one mouse per genotype) (discussed in detail below).

The deleted POMC allele construct was introduced into embryonic stem (ES) cells by electroporation and from there into the mouse germline, generating strain *Pomc*^{bm2ute}. When the mutation was backcrossed into the inbred 129/SvEv background, homozygous POMC mutants were born to heterozygous parents at one quarter (39 wildtype, 80 heterozygotes, 10 mutants) of the frequency expected for a recessive mutation, indicating that concurrent lack of all of the embryonic derived POMC peptides is compatible with survival throughout prenatal development in only a fraction of the animals.

Female POMC null mice are fertile and carry heterozygous and wild-type pups to term. When heterozygous POMC males are mated to homozygous POMC mutant females,

homozygous mutant, but not heterozygous, offspring die within the first few hours after birth.

During the first postnatal month homozygous mutants are superficially indistinguishable from their wildtype littermates. In the second month, mice lacking
5 POMC peptides start to gain weight visibly, and by the third postnatal month their weights are about twice those of their wildtype littermates (Fig. 2A; weight measurements were taken from male mice of each genotype; at 2 months $n=4$, $P<0.0005$; at 3 months $n=3$, $P<0.005$). The weight gain is accompanied by both a slight, but significant, increase in body length (Fig. 2B; measurements (snout to root of tail) were taken from 3-4 months
10 old female mice, 6 mice per genotype ($P<0.001$)) and a large increase in serum leptin levels (Fig. 2C). In this latter experiment, serum leptin levels were determined (in duplicates) from blood samples collected retroorbitally from 6-8 months old, individual, male and female mice. Average weights were 30.9 g for wildtype mice, 31.7 g for heterozygotes, and 55.9 g for homozygotes. Interestingly, heterozygote mice show elevated levels of
15 serum leptin, but do not display significantly increased body weight. The elevated leptin levels in the normal weight heterozygotes suggest a homeostatic balance between leptin levels and POMC peptide levels: the decreased POMC peptide levels are compensated by increased leptin. The mechanism and significance of such a relationship suggest a paracrine feed-back loop.

20 It was also noticed that the POMC mutant mice raised on a high fat breeder chow gained weight faster than mice raised on standard chow. Wildtype and mutant females (3 per test group) were given unlimited access either to standard or to breeder chow (4.5% and 9% fat, respectively). Figs 2D and 2E show weight change (2D) and food intake (2E) during one week. Food intake in the "high fat diet" groups was measured in bulk for all
25 three mice. Fig. 2D shows that the mutant mice gained 3 grams more per week on a high fat diet versus a standard diet (3.8 g versus 0.8 g), while wildtype mice gained 0.2 g more on a high fat diet versus a standard diet (0.7 g versus 0.5 g). Fig. 2E shows that the food intake by POMC mutants increased with high fat diet by 2.4 g (30.3 g versus 32.7 g), while the food intake by wildtype littermates decreased with high fat diet by 2.2 g (23.5
30 g versus 21.3 g). Under either dietary condition mutant mice lacking POMC have an increased food intake compared to wildtype littermates. These results suggest that POMC

derived peptides mediate both food intake and bodily food deposit. Wildtype mice regulate their food intake according to the diet, i.e., they decrease intake with a higher caloric supply, and they adjust their metabolism (food deposit versus burning) to keep their body weight constant. In contrast, mice lacking POMC show a deficit in both of these aspects with the result of increased body weight: they have an increased food uptake and they lack the ability to catabolize dietary fat.

Another visible difference between POMC null mutant mice and the wildtype mice is the yellowish pigmentation of mutant mice (data not shown), which is especially pronounced on the belly. MC1-R in melanocytes is normally stimulated by α -MSH, resulting in synthesis of eumelanin (black/brown) pigment (Burchill et al., 1986, *J. Endocrinol.* 109:15-21). Antagonism of MC1-R by the agouti-signaling protein (ASP) overexpressed in A^y mice results in whole body yellow coat color (Lu et al., 1994, *Nature* 371:799-802). A loss-of-function mutation in the *Mclr* gene in the recessive yellow mouse (*e/e*) (Robbins et al., 1993, *Cell* 72:827-834) and in cattle (Joerg et al., 1996, *Mamm. Genome* 7:317-318) causes yellow coat and red coat, respectively. The human patients with POMC null mutations have red hair as well (Krude et al., *ibid.*). In the POMC null mice, the change in pigmentation is subtle, in that the coat covering the sides and belly is more yellow than in wildtype littermates, and the tips of the hairs at the back have a yellowish tinge. These pigmentation differences in mutants become more pronounced during adulthood. The fact that in the mouse, lack of the ligand (POMC) does not result in a phenotype congruent with lack or antagonism of MC1-R, suggests the presence of other ligands for this melanocortin receptor. Alternatively, this result could be explained if there is a ligand-independent constitutive activity of the receptor.

Next, the effect of a complete lack of ACTH on adrenal function was determined. Serum corticosterone levels (Fig. 3A) were determined by RIA from blood samples collected retroorbitally from 6-7 month old mice (n=7 for wildtypes, n=6 for heterozygotes, n=5 for mutants). Serum aldosterone levels (Fig. 3B) were determined in trunk blood samples from 7-8 month old mice (n=1 for wildtypes, n=2 for heterozygotes, n=3 for mutants). Plasma catecholamine levels (Figs. 3C-3E) were determined in trunk blood samples from 7-8 month old mice (n=4 for wildtype mice, n=3 for mutant mice).

Fig. 1C shows an RIA analysis of serum ACTH levels in F₂ male littermates (measurements in triplicates, one mouse per genotype). Blood was collected retroorbitally and serum was analyzed by RIA following the provider's instructions (ICN, corticosterone; IncStar, ACTH; Linco, Leptin). Fig. 1C shows that ACTH levels in the mutant animal were below the sensitivity of the assay, indicating that the coding region for all POMC peptides had been deleted.

Serum corticosterone and aldosterone levels were below detection (Figs. 3A and 3B), despite considerable stressing of mice during blood collection, indicating an absolute necessity for POMC derived peptides for adrenal cortical function. Here again, heterozygotes show a gene dosage effect, suggesting fine-tuned regulation by POMC peptides. When plasma catecholamine basal levels were measured (Figs. 3C-3E), epinephrine was significantly lower in POMC mutants versus wildtype mice (Fig. 3C; $p < 0.006$), while levels of norepinephrine were not significantly altered (Fig. 3D; $p < 0.27$) and dopamine levels were slightly increased in mutants compared to wildtypes (Fig. 3E; $p < 0.06$). In cases of dysfunction of the adrenal medulla, other chromaffine tissues expressing catecholamines increase production to compensate; epinephrine, however, is almost exclusively produced by the adrenal medulla. The significant decrease of epinephrine indicates a severe dysfunction and/or lack of the adrenal medulla in POMC deficient mice. Looking for adrenal glands proved to be impossible: mutant mice had no macroscopically discernible adrenal glands. For histological analysis, tissues from the fat pad surrounding the kidney were collected and immediately placed into formalin. Sectioning (5 μ m thickness) and staining were carried out by American Histolab, Inc., Gaithersburg, Maryland. Histological examination of the fat pad surrounding the kidney and presumably containing adrenal tissue revealed areas of tissue reminiscent of rudimentary adrenal medulla or adrenal cortex (data not shown). However, immunohistochemical staining with antibodies against key enzymes in catecholamine synthesis (PNMT and TH) were negative (data not shown).

The lack of a normal adrenal gland structure in POMC null mice points to a critical role of POMC derived peptide(s) in adrenal development. POMC adrenocorticotropin (ACTH) of pituitary origin is the only known ligand for the MC2-R in the adrenal gland. It is surprising that loss of ligand (ACTH) results in loss of the tissue expressing its

receptor (MC2-R). Without being bound by theory, the present inventors believe that it may be more likely that another POMC factor distinct from ACTH plays a role as trophic factor in adrenal gland development. Candidate peptides would be peptides derived from the N-terminal non- γ -MSH region of POMC (N-POMC₁₋₂₈, N-POMC₂₋₅₉), which have
5 been implicated in the physiological control of adrenal growth (Estivariz et al., 1982, *Nature* 297:419-422). This can be tested by reconstituting the POMC null mice with candidate peptides. It may also be possible at that point to determine whether the lack of adrenal medulla is a consequence of the lack of POMC peptides, or of adrenal cortical structure, or of adrenal cortical factors (i.e., corticosterone).

10 The phenotype of obesity, adrenal insufficiency, and altered pigmentation, makes the POMC null mouse a model for the human POMC null syndrome. In the human POMC deficient patients and in the mouse POMC mutant, homozygotes are born within the normal range of weight and size. Development of obesity starts at 4 to 5 months in the reported cases in humans (Krude et al., 1998, *Nat. Genet.* 19:155-157), and at 1
15 month in POMC null mice. This time course of obesity is also similar to that seen in *fat/fat* mice, which lack carboxypeptidase E, a prohormone processing enzyme (Naggert et al., 1995, *Nat. Genet.* 10:135-142). A defect in processing of POMC could explain the obesity component of the *fat/fat* phenotype.

In the human POMC deficient patients, ACTH deficiency results in
20 hypocortisolism and, if untreated, in death. In the POMC null mice, the present inventors were unable to detect corticosterone in serum, even under moderate stress conditions. In contrast to humans, mice that develop with maternal but without endogenous corticosterone are viable. A similar observation has been made in mice lacking corticotropin releasing factor, CRH, which develop normally despite very low levels of
25 corticosterone (Muglia et al., 1995, *Nature* 373:427-432). As in offspring from CRH null females, homozygous offspring from POMC null mutants die within the first hours after birth. This is probably due to defective lung maturation with the lack of corticosterone, as has been demonstrated for the CRH null mutants.

Corticosteroids are known to increase food intake (Tempel et al., 1994, *J. Neuroendocrinol.* 6:479-501) and to decrease energy expenditure (Strack et al., 1995, *Am. J. Physiol.* 268:R1209-1206). POMC null mice have no detectable corticosterone,
30

yet they are obese. This is so far the only situation where obesity occurs in the absence of corticosterone. In all other forms of murine obesity, corticosterone is at normal or elevated levels. In fact, the excessive obesity in leptin-deficient mice is largely due to the hypercortisolism in this mouse and adrenalectomy blocks the development of excessive obesity in lep^{ob}/lep^{ob} mice (Solomon et al., 1973, *Endocrinology* 93:510-512 and Tokuyama et al., 1989, *Am. J. Physiol.* 257:E139-144).

Lack of ligands for the melanocortin receptors in POMC-deficient mice replicate fully or partly the effects seen in mice lacking the receptors MC4-R or MC1-R, respectively. In a preliminary analysis, POMC-deficient mice also replicate the defective water repulsion and thermoregulation seen in mutant mice lacking MC5-R (data not shown). The present results provide a strong indication that POMC peptides are the physiological ligands for at least some MC5-R mediated functions.

Example 2

The following example demonstrates that administration of a POMC peptide analog to a mouse having obesity resulted in significant weight loss.

To test initially for the effect of peripheral melanocortins on weight change, we selected the stable agonist [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH (4-13) (described in Cody et al., 1985, *J. Med. Chem.* 28, 583-588; incorporated herein by reference in its entirety). Briefly, [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH (4-13) amide, having the cysteines connected by a disulfide bridge, was obtained from Peninsula Laboratories, CA. Lyophilized powder was dissolved in water at 1 mg/ml, which was diluted in PBS to 10 μ g/mL. During the experiments, mice were maintained on a normal 12h/12h light/dark cycle with food and water *ad libitum*. Mice were fed standard laboratory rodent diet (#5001).

Daily intraperitoneal injections of one microgram (~ 1 nmol) of this MSH-agonist (0.1 ml in PBS delivered one to two hours before the onset of darkness) led to a significant weight loss (38% of excess weight within one week, and 46% of excess weight by 2 weeks) in mutant female mice ($p < 0.1$ at day 8, $p < 0.05$ at day 16), but caused no significant weight loss in wildtype littermates (Fig. 4A). Fig. 4A shows the mean change in body weight from the pretreatment weight in grams for groups of three mice (POMC homozygous mutant and wildtype female mice) for the 16-day period of treatment. When

the MSH injections were stopped, mutant mice started to gain weight after about 10 days, and reached close to their pretreatment weight after another two weeks (Fig. 4B).

In order to see whether the α -MSH analog has an effect on food intake, we compared weight change and food intake in these mice for one week (see bars in Figs. 4A and 4B) under MSH analog treatment and after MSH analog treatment was stopped (Figs. 4C and 4D). During one week under MSH analog treatment mutant mice lost 0.5 g, while wildtype littermates gained 0.3 g; the food intake during this time was equivalent in both groups (20.7 g in wildtypes, and 22.7 g in mutants). After MSH analog treatment had been stopped for two weeks, mutant mice now gained 1.7 g in one week, while wildtype littermates kept their overall weight gain of 0.3 g; food intake now differed significantly between the two groups, with mutants taking up 11.5 g more than wildtypes (35.7 g versus 24.2 g; $p < 0.005$). These results show that lack of α -MSH correlates with food intake, although this experiment did not distinguish whether MSH influences body weight primarily through food intake or in combination with a direct effect of melanocortins on adipocytes (inhibition of free fatty acid uptake or stimulation of lipolysis).

An effect of MSH could also be seen on coat pigmentation. The coats of mice treated with MSH for two weeks lost their yellowish tinge (data not shown). Yellow coat pigmentation gradually reappeared after MSH treatment was terminated (data not shown).

20 Example 3

The following example provides evidence that the major component of weight regulation through the melanocortinergeric pathway is not through central, appetite regulating effects.

To consider further the question of central, appetite regulating effects of melanocortins versus peripheral (possibly lipolytic or free fatty acid uptake) effects, weight change and food intake in wildtype and POMC null mutant mice (3 female mice per group) under three experimental conditions were measured (Figs. 5A-5D): (1) standard mouse diet, no treatment; (2) standard mouse diet, MSH analog intraperitoneally (1 or 2 μ g, once daily); and (3) high fat diet (#5020), no treatment. With respect to weight regulation, wildtype mice are completely capable of maintaining their body weight constant under those varying conditions (Fig. 5A). Mutant mice lacking POMC peptides

gain weight with standard diet, lose excess weight when treated with MSH analog peripherally, and gain more than double the weight with high-fat diet as they gain with standard diet (Figs. 5C). Table 1 shows the statistical significance of the comparisons between genotype, diet, and MSH analog treatment with respect to weight change and food intake. P values were determined by ANOVA. If the major component of weight regulation through the melanocortineric pathway was the regulation of feeding behavior, the observed changes in body weight in POMC null mutant mice should be paralleled by a similar pattern in food uptake. This, however, was not observed (Figs. 5B and 5D and Table 1). Rather, the following observations were made: (1) compared to wildtype mice when fed a standard diet, POMC mutant mice are hyperphagic, and they gain weight, yet with MSH analog treatment, they lose weight despite still being hyperphagic; (2) MSH analog treatment decreases food intake in both wildtype and mutant mice, yet only mutant mice lose significant weight; (3) when fed a high fat diet, food intake is unchanged in mutant and wildtype mice compared to feeding on standard diet, as well as compared between mutant and wildtype mice, yet mutant mice gain significant weight, both compared to standard diet and compared to wildtype mice.

TABLE 1

Comparisons	weight change	P value	food intake	P value
wildtype mice				
standard diet v. standard diet & MSH analog treatment	~	>0.05	↓	<0.05
standard diet v. high fat diet	~	>0.05	~	>0.05
mutant mice				
standard diet v. standard diet & MSH analog treatment	↓	<0.005	↓	<0.05
standard diet v. high fat diet	↑	<0.05	~	>0.05
standard diet				
wildtype v. mutant	↑	<0.05	↑	<0.05
standard diet & MSH analog treatment				
wildtype v. mutant	↓	<0.05	↑	<0.05
high fat diet				
wildtype v. mutant	↑	<0.0005	~	>0.05

In experiments assaying transient regulation of feeding behavior, 3 nmol MSH agonist were needed to see a significant effect on food intake when applied intracerebroventricularly; and 100 nmol of agonist were needed when administered intraperitoneally (Kastin et al., *ibid.*). This is 100 times more than was applied in the

present experiments, assaying weight change. Furthermore, the level of MSH agonist that was given peripherally in these experiments is approximately that of the endogenous melanocortin in a normal mouse.

5 The weight losses and gains of POMC mutant mice in the present experiments cannot be explained solely by their feeding behavior. Rather, these data are consistent with both central and peripheral actions of melanocortins. POMC-deficient mice show both increased food intake and dysregulation of metabolism (fat storage/release). Treatment with peripheral melanocortin agonist results in significant weight loss in mutant obese, but not in wildtype, non-obese mice. This may be either a direct effect of
10 melanocortins on adipocytes (inhibition of free fatty acid uptake and/or stimulation of lipolysis) or an indirect effect mediated by another mechanism.

The adult-onset obesity resulting from overexpression of agouti signaling protein in *A^y* mice (Lu et al., *ibid.*), or from overexpression of agouti related protein (AGRP or agouti related transcript, ART) in transgenic mice (Graham et al., *ibid.* and Ollmann et al.,
15 *ibid.*), are generally interpreted as consequences of antagonism of α -MSH on hypothalamic MC4-R. However, without being bound by theory, the present inventors believe that the competition for binding sites with α -MSH may also be in the periphery, given the present results taken together with data which shows that agouti stimulates adipogenesis (Jones et al., 1996, *Am. J. Physiol.* 270:E192-196) and antagonizes
20 melanocortin-mediated lipolysis (Xue et al., 1998, *Faseb J.* 12:1391-1396) directly in adipocytes. Another observation underlying the importance of peripheral mechanisms of weight regulation is that of leptin treatment in the *obese* mouse, which leads to a loss in body weight not accounted for by a simple decrease of food intake (Levin et al., 1996, *Proc. Natl. Acad. Sci. USA* 93:1726-1730). The lipolytic effects of melanocortins in
25 rabbits have been described (Kastin et al., 1975, *Pharmacol. Biochem. Behav.* 3:121-126 and Richter et al., 1987, *Neuropeptides* 9:59-74). Melanocortins circulate in the periphery and their receptors are found in peripheral tissues; specifically, melanocortin receptors are found on adipocytes (Boston et al., 1996, *Endocrinology* 137:2043-2050).

Example 4

The following example illustrates the effect of α -MSH analog treatment in leptin-deficient *obese* mice.

To assess a more general effect of peripheral melanocortin on adipocytes, another genetic form of obesity, in *lep^{ob/ob}* mice, was treated with the α -MSH analog. In this experiment, the mice received leptin or the α -MSH analog alone, and in combination. Briefly, obese *lep^{ob/ob}* mice at age 2 months (2 per group) received daily either: (1) 3 μ g of α -MSH analog (described in Examples 2 and 3 above); (2) 3 μ g of recombinant mouse leptin; (3) 3 μ g of α -MSH analog and 3 μ g of recombinant mouse leptin in combination; or (4) saline. The compounds were delivered intraperitoneally once daily, 1-2 hours before the onset of darkness. Fig. 6 shows the total weight change over a period of 10 days.

Fig. 6 shows that while the doses of leptin used in this experiment had little effect on preventing further weight gain compared to untreated controls, the α -MSH analog slowed weight gain by almost half. The combination of leptin and MSH had a synergistic effect in that it prevented weight gain almost completely. As in the POMC obesity model described in Example 3, in this obesity model the differences in weight gain do not simply correlate with food intake (data not shown).

Example 5

The following example demonstrates that administration of leptin to obese *lep^{ob/ob}* mice induces almost normal levels of circulating MSH, that peripherally administered MSH analog decreases weight gain in obese *lep^{ob/ob}* mice, and that peripherally administered MSH analog increases thermal homeostasis in obese *lep^{ob/ob}* mice.

Leptin, the product of the *ob* gene in mouse, is produced by adipocytes. It circulates to the hypothalamus where it binds to cells expressing the leptin receptor, the product of the *db* gene in mouse. This leptin binding leads, directly or indirectly, to the secretion of melanocyte stimulating hormone (MSH), which in turn binds to neurons expressing the melanocortin 4 receptor (MC4-R). These neurons then suppress appetite. This outline is based on the phenotypes of spontaneous and induced mouse mutants as well as on homologous mutations in humans. Interpretations are in agreement as to leptin

being the signal from the fat stores to the central nervous system, and further with respect to an integration of signals with the net result of appetite regulation. However, without being bound by theory, the present inventors believe that there are significant aspects of the phenotypes of these mutants that suggest a greater complexity of body weight homeostasis, specifically the integration of appetite and metabolism. The present
5 inventors believe that there is a factor which comes from the central nervous system to the periphery which mediates this integration. There are several reasons which have led the present inventors to believe that MSH is this factor.

First, the *pomc/pomc* mutant, which was produced by the present inventors and
10 which is described herein, completely lacks MSH, and shows phenotypes suggestive of altered lipid metabolism. When the fat content of the diet increases, the mice paradoxically eat more and gain weight much more rapidly. This weight gain, which occurs in excess of food intake, argues for a pathologically "increased metabolic efficiency". When these mutants are treated by peripheral administration of an α -MSH analog as demonstrated in
15 the examples above, the mice lose weight, but more than anticipated from the decrease in food intake, again consistent with an increased "metabolic efficiency".

Second, leptin deficient mice (*ob/ob*) show an "increased metabolic efficiency" which precedes the onset of obesity. These mutants show: (1) weight gain when pair-fed with normal controls; (2) longer survival in a fast than normal mice of equal initial weight;
20 and (3) decreased ability to maintain body temperature at 4°C. Taken together, these data suggest that the *ob/ob* mice have adjusted their metabolism to conform to their known fat stores, that is, in the absence of leptin, they sense no fat stores. The mechanism for such an adjustment is unknown at present.

In order to further address the issues related to body weight homeostasis, especially the possibility of the integration of appetite and "metabolic efficiency" through
25 the POMC pathway, the present experiments were designed.

An inductive role for leptin in the secretion of MSH is suggested by the low levels of circulating MSH in *ob/ob* mutants, by the expression of leptin receptors on POMC expressing neurons of the hypothalamus, by the correlation of hypothalamic POMC
30 mRNA with leptin levels in fasting wildtype mice and in *ob/ob* as well as leptin-reconstituted *ob/ob* mice, and by the ability of MSH administered

intracerebroventricularly to suppress transiently the hyperphagia in *ob/ob* mutant mice. To test the inductive ability of leptin on circulating MSH levels, *ob/ob* mutants (*ob/ob* mutant mice (C57BL/6J-*Lep^{ob}*) and congenic controls were purchased from the Jackson Laboratory, Bar Harbor, ME) were treated with leptin (7 microgram/day) or with vehicle alone (Murine recombinant leptin was kindly provided by Dr. A.F. Parlow through the National Hormone and Pituitary Program (NHPP); hormones were diluted to 70 micrograms per milliliter in PBS; mice were injected intraperitoneally with 0.1 mL). Two hours after the tenth daily injection, blood samples were drawn from the retro-orbital sinus and analyzed for MSH levels by RIA following the manufacturer's instructions (Peninsula Laboratories, Belmont, California). While circulating MSH in vehicle treated *ob/ob* mutants were similar to the very low levels reported previously, the MSH levels in leptin treated *ob/ob* mutants approached those found in normal control mice (Fig. 7).

Leptin deficient (*ob/ob*) mutants show *both* hyperphagia and "increased metabolic efficiency" as witnessed by their ability to gain weight even when pair-fed with normal congenic controls. To determine the effects of leptin and MSH on food intake and weight gain, four sets of *ob/ob* mutants were treated with leptin, an MSH analog, both together, or vehicle alone. The MSH analog [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH (4-13) was purchased from Peninsula Laboratories (Belmont, California). Mice were treated with daily injections of 7 micrograms of each, both or neither. The results are shown in Fig. 8. Fig. 8 shows that both leptin treatment and MSH analog treatment effectively decreased weight gain. Surprisingly, the effect of the MSH analog was greater on weight gain than on food intake, indicating a reversal of the "increased metabolic efficiency" of the *ob/ob* mutant mice (Figs. 8 and 9).

In 1977, the decreased ability of *ob/ob* mutants to maintain body temperature at 4° C was noted. This *preceded* the onset of obesity in these mice. In view of the evidence that MSH regulates adipocyte metabolism, the present inventors hypothesized that the low levels of circulating MSH in leptin deficient (*ob/ob*) mutants was responsible for the impaired thermal regulation. To test this, *ob/ob* mutants were injected with 7 micrograms of MSH analog or vehicle only as described above. The mice were left without food for 5 hours and then exposed to 4° C for 65 minutes. Their core temperatures were measured periodically by transfer to a coldroom (4° C) where core temperatures were measured

using a digital thermometer fitted with a rectal probe (Atkins Technical Inc., Gainesville, Florida). As seen in Fig. 10, the mice treated with the MSH analog maintained their core temperature much better than did the vehicle treated control *ob/ob* mutants. As the mice had no opportunity to eat between injection of the MSH analog and the cold challenge, food intake cannot be responsible for the altered thermal regulation.

In summary, these experiments have shown: (1) that injection of leptin (7 micrograms) induces almost normal levels of circulating MSH in *ob/ob* mutants; (2) that peripherally administered MSH analog decreases weight gain in *ob/ob* mutants; and (3) that peripherally administered MSH analog increases thermal homeostasis in *ob/ob* mutants.

In view of these results, the present inventors, without being bound by theory, propose the following modifications to the leptin-POMC scheme presented above. First, the present inventors have demonstrated that MSH mediates *both* a decrease in appetite (via a central mechanism) and a decrease in "metabolic efficiency" (via a peripheral mechanism). These responses are complementary responses to sufficient fat stores. Absent of sufficient fat stores, an organism may be expected both to eat more and to expend less energy. Like the *ob/ob* mutants, the *pomc/pomc* mutants show an "increased metabolic efficiency" which can be reversed by peripherally administered MSH analog, as described in the present invention. The direct effect of MSH on appetite suppression is assumed to be mediated through MC4R expressing neurons, while the decrease in "metabolic efficiency" is postulated to be mediated by peripheral cells expressing melanocortin receptors, especially adipocytes.

The decreased ability to thermoregulate of *ob/ob* mutants reflects their inability to mobilize fat without the signal (MSH) from the center to the periphery to do so; this MSH signal is dependent on a leptin signal indicating sufficient fat stores. Decreased thermoregulation can be alleviated either by exogenous leptin, which in turn increases circulating MSH, or by direct administration of exogenous MSH.

Again without being bound by theory, the present inventors believe that the presence of melanocortin receptors on adipocytes and the ability of MSH at physiological levels to affect metabolism are consistent with a direct effect of MSH in the periphery. Indeed, the differences between leptin treated and MSH analog treated *ob/ob* mice are

consistent with *two* effects of MSH, one central (appetite suppressing) and one peripheral (metabolic). In addition, the inability of peripheral MSH analog to supplement the weight reducing effect in *ob/ob* mice of a leptin dose sufficient to induce normal MSH levels is consistent with the ability of leptin, under normal circumstances, to induce levels of central and peripheral MSH balanced for appetite and metabolism. Whenever this is not the case (e.g. *ob/ob*, and *pomc/pomc* mutants) peripheral administration of an MSH analog can change the "metabolic efficiency".

While various embodiments of the present invention have been described in detail, it is apparent that modifications and adaptations of those embodiments will occur to those skilled in the art. It is to be expressly understood, however, that such modifications and adaptations are within the scope of the present invention.

What is claimed is:

1. A method to regulate body weight in an animal, comprising administering to said animal a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein said POMC compound is administered to the periphery of said animal
5 in an amount effective to measurably regulate body weight in said animal, whereby administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

2. A method for inhibition of free fatty acid uptake and/or stimulation of lipolysis in an animal, comprising administering to the periphery of an animal a POMC
10 compound in an amount effective to produce a result selected from the group consisting of stimulation of lipolysis and inhibition of fatty acid uptake.

3. A method of regulating the body weight of an animal, comprising administering to an animal a POMC compound in an amount effective to bind to POMC receptors expressed by said animal in said animal's peripheral tissues, said effective
15 amount:

(a) being insufficient to substantially change the appetite of said animal after said step of administering as compared to before said step of administering;

(b) being between about 0.1 µg and about 10 mg per kg of body weight of said animal;

(c) being sufficient to affect a biological activity selected from the group consisting of:
20

(i) lipolysis; and,

(ii) uptake of fatty acids by adipocytes in said animal; and,

(d) being effective to measurably increase or decrease the body weight
25 of said animal after said compound has been administered to said animal.

4. A method for regulating metabolic efficiency in an animal, comprising:

(a) measuring serum MSH levels in an animal;

(b) identifying animals having serum MSH levels of less than about 0.1 ng/ml; and,

(c) administering to the periphery of said animals identified in (b) a composition comprising a compound selected from the group consisting of a
30

POMC compound and leptin, wherein said compound is administered in an amount effective to increase serum MSH levels in said animal to level effective to produce a result selected from the group consisting of stimulating lipolysis and inhibiting fatty acid uptake in said animal.

5 5. A method for treating an affective and mood disorder in an animal, comprising administering to an animal at risk for or suffering from an affective mood disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein said POMC compound is administered to the periphery of said animal in an amount effective to measurably ameliorate said disorder in said animal, whereby
10 administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

 6. A method to treat an obesity-associated disorder in an animal, comprising administering to an animal suffering from or at risk for an obesity-associated disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein
15 said POMC compound is administered to the periphery of said animal in an amount effective to measurably decrease body weight or weight gain in said animal, whereby administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

 7. A method for treating a reproductive disorder in an animal, comprising
20 administering to an animal at risk for or suffering from a reproductive disorder a therapeutic composition comprising a proopiomelanocortin (POMC) compound, wherein said POMC compound is administered to the periphery of said animal in an amount effective to prevent or ameliorate said disorder, whereby administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

25 8. A method to control undesired body weight which is a side effect resulting from administration of a pharmaceutical compound, comprising administering to an animal at risk of or suffering from undesired body weight which is a side effect resulting from administration of a pharmaceutical compound, a therapeutic composition comprising a proopiomelanocortin (POMC) compound wherein said POMC compound is administered
30 to the periphery of said animal in an amount effective to measurably decrease body weight

or weight gain in said animal, whereby administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

9. A method to regulate body weight in an animal, comprising administering to said animal a food composition comprising a proopiomelanocortin (POMC) compound, wherein said food composition is effective to measurably regulate body weight in said animal, and wherein delivery of said compound to the central nervous system of said animal is minimized.

10. A method to increase the body weight and/or mass in an animal having an eating disorder, comprising administering to said animal a therapeutic composition comprising a proopiomelanocortin (POMC) antagonist compound, wherein said POMC compound is administered to the periphery of said animal in an amount effective to measurably increase body weight or reduce body weight loss in said animal, whereby administration of said compound minimizes delivery of said compound to the central nervous system of said animal.

11. A method to regulate body weight in an animal, comprising modulating the activity of a melanocortin receptor selected from the group consisting of melanocortin 2-receptor and melanocortin 5-receptor.

12. A method for identifying compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis, comprising:

- a. contacting a putative regulatory compound with a cell which expresses a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R);
- b. detecting whether the putative regulatory compound increases said melanocortin receptor activity;
- c. contacting said putative regulatory compound with a cell which expresses a melanocortin 4-receptor (MC4-R); and,
- d. detecting whether the putative regulatory compound increases MC4-R activity;

wherein putative regulatory compounds that induce greater MC2-R activity or MC5-R activity as compared to MC4-R activity are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis.

13. A method for identifying compounds that increase body weight by regulating peripheral pathways of energy homeostasis, comprising:

5 a. contacting a cell which expresses a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates said melanocortin receptor in the presence and absence of a putative regulatory compound;

b. detecting whether said putative regulatory compound inhibits said melanocortin receptor activity;

10 wherein putative regulatory compounds that inhibit said melanocortin receptor activity are identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis.

14. A method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising:

15 a. contacting a putative regulatory compound with a cell which expresses a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R);

b. detecting whether the putative regulatory compound binds to said melanocortin receptor;

20 c. administering compounds which bind to said melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of said test animal;

25 wherein putative regulatory compounds that interact with the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which regulate body weight by regulating peripheral pathways of energy homeostasis.

15. A method for identifying compounds that increase body weight by regulating peripheral pathways of energy homeostasis, comprising:

30 a. contacting a cell which expresses a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R) with a POMC compound which binds to and activates said melanocortin receptor in the presence and absence of a putative regulatory compound;

b. detecting whether said POMC compound binds to said melanocortin receptor;

c. administering compounds which bind to said melanocortin receptor to a non-human test animal and detecting whether the putative regulatory compound regulates the body weight of said test animal;

wherein putative regulatory compounds that bind to the melanocortin receptor and that regulate the body weight of the test animal are identified as compounds which increase body weight by regulating peripheral pathways of energy homeostasis.

16. A method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising:

a. contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R);

b. detecting expression of the reporter gene product;

c. contacting a putative regulatory compound with a cell or cell lysate containing a reporter gene operatively associated with a regulatory element of a melanocortin 4-receptor (MC4-R); and,

d. detecting expression of the reporter gene product;

wherein putative regulatory compounds that increase expression of the reporter gene product of (b) as compared to the reporter gene product of (d) are identified as compounds that regulate body weight by preferentially regulating peripheral pathways of energy homeostasis.

17. A method for identifying compounds that regulate body weight by regulating peripheral pathways of energy homeostasis, comprising:

a. contacting a putative regulatory compound with a cell or cell lysate containing transcripts of a peripheral melanocortin receptor selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R); and,

b. detecting translational inhibition of the melanocortin receptor transcript;

wherein putative regulatory compounds that inhibit said melanocortin receptor transcript are identified as compounds that increase body weight by regulating peripheral pathways of energy homeostasis.

18. A method for identifying compounds that regulate peripheral pathways of energy homeostasis, comprising:

(a) contacting a putative regulatory compound with an isolated adipocyte;

and,

(b) detecting putative regulatory compounds that bind to a peripheral melanocortin receptor on said adipocyte, wherein putative regulatory compounds that bind to melanocortin receptors on said adipocytes are identified as compounds that regulate body weight by regulating peripheral pathways of energy homeostasis.

19. A method to identify compounds useful in regulating peripheral and central pathways of energy homeostasis, comprising:

a. administering a compound to be evaluated to a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein said genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in said animal; and,

b. evaluating physiological changes in said genetically modified non-human animal as compared to a non-human animal selected from the group consisting of: (a) a second genetically modified non-human animal comprising a genetic modification within at least one allele of its *Pomc* locus, wherein said genetic modification results in a reduction in proopiomelanocortin (POMC) peptide action in said animal; and (b) a third non-human animal having a genome comprising a wild-type *Pomc* locus at two alleles.

20. A method for studying the molecular and biochemical events associated with obesity, comprising:

a. harvesting cells, tissues or body fluids from a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein said genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in said animal; and,

- b. comparing said cells, tissues or body fluids from said genetically modified non-human animal to cells, tissues or body fluids from a wild-type sibling of said genetically modified non-human animal.

5 21. A therapeutic composition that regulates the peripheral melanocortinerbic and/or leptinerbic pathways of energy homeostasis in an animal, comprising:

- a. a first body weight regulating agent that is a proopiomerelanocortin (POMC) compound; and,
- b. a second body weight regulating agent that is not a proopiomerelanocortin (POMC) compound.

10 22. A food composition that regulates the peripheral melanocortinerbic and/or leptinerbic pathways of energy homeostasis, comprising a proopiomerelanocortin (POMC) compound.

15 23. A genetically modified non-human animal useful for studying peripheral and central pathways of energy homeostasis, said genetically modified non-human animal comprising a genetic modification within at least one allele of its *Pomc* locus, wherein said genetic modification results in a reduction in proopiomerelanocortin (POMC) peptide action in said animal.

20 24. A genetically modified mouse useful for studying peripheral and central pathways of energy homeostasis, wherein said genetically modified mouse is produced by a method comprising the steps of:

- a. isolating from a source of murine genomic DNA a nucleic acid molecule comprising SEQ ID NO:7;
- b. deleting a nucleic acid sequence comprising SEQ ID NO:7 from said nucleic acid molecule to form a genetically modified nucleic acid molecule;
- 25 c. inserting a selectable marker into said genetically modified nucleic acid molecule to create a targeting vector;
- d. transfecting said targeting vector into embryonic stem cells;
- e. selecting embryonic stem cells from step (d) which have incorporated said targeting vector at a target locus comprising SEQ ID NO:7 by
30 homologous recombination;

- f. inserting said embryonic stem cells selected in step (e) into non-human animal blastocysts;
- g. impregnating a female surrogate with said non-human animal blastocysts to produce said genetically modified mouse.

5 25. A method of producing a genetically modified non-human animal useful for studying peripheral and central pathways of energy homeostasis, comprising:

- a. introducing into an embryonic stem cell of a non-human animal a targeting vector comprising a *Pomc* locus containing a modification of a nucleic acid sequence sufficient to result in a reduction in proopiomelanocortin (POMC) peptide action in said animal; and,
- 10 b. obtaining progeny having said modification stably incorporated into their genome, wherein said modification results in a reduction in expression of proopiomelanocortin (POMC) peptides by said animal.

15 26. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is selected from the group consisting of a melanocortin compound and a lipocortin compound.

 27. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is a melanocortin compound.

20 28. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is selected from the group consisting of melanocyte stimulating hormone (MSH), a fragment of MSH, a homologue of MSH, a peptide mimetic of MSH, a non-peptide mimetic of MSH, and a fusion protein comprising an MSH protein or fragment thereof.

25 29. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is selected from the group consisting of α -MSH, β -MSH and γ -MSH.

 30. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is a peptide mimetic of MSH.

30 31. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said compound is an analog of a peptide having an amino acid sequence represented herein by SEQ ID NO:2.

32. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound is an α -MSH analog selected from the group consisting of:

- a. [Ac-Cys⁴, D-Phe⁷, Cys¹⁰] α -MSH, wherein said Cys residues are connected by a disulfide bond;
- 5 b. Ac-[Nle⁴, X_{aa}⁵, His⁶, X_{aa}⁷, Arg⁷, Trp⁹, X_{aa}¹⁰]-NH₂ (SEQ ID NO:3) wherein X_{aa}⁵ is Glu or Asp, X_{aa}⁷ is Phe or D-Phe and X_{aa}¹⁰ is a dibasic amino acid; Lys; ornithine; 2,4,-diaminobutyric acid; or 2,3 diaminopropionic acid (Dpr);
- c. Ac-[Cys⁴, Cys¹⁰] α -MSH₁₋₁₃NH₂;
- 10 d. R₁-W-X-Y-Z-R₂,
wherein R₁ is selected from the group consisting of Ac-Gly-, Ac-Met-Glu-, Ac-Nle-Glu- and Ac-Tyr-Glu-;
W is selected from the group consisting of -His- and -D-His-;
X is selected from the group consisting of -Phe-, -D-Phe-, -Tyr-, -D-Tyr-,
15 (-pNO₂)D-Phe⁷-;
Y is selected from the group consisting of -Arg- and -D-Arg-;
Z is selected from the group consisting of -Trp- and -D-Trp-; and,
R₂ is selected from the group consisting of -NH₂, -Gly-NH₂, and -Gly-Lys-NH₂;
- 20 e. Ac-Ser-Tyr-Ser-M-Glu-His-D-Phe-Arg-Trp-Gly-Lys-Pro-Val-NH₂ (SEQ ID NO:4),
wherein M is selected from the group consisting of Met, Nle, and Cys;
- f. [Nle⁴, D-Phe⁷]- α -MSH;
- g. [Nle⁴, D-Phe⁷]- α -MSH₄₋₁₀;
- 25 h. [Nle⁴, D-Phe⁷]- α -MSH₄₋₁₁;
- i. [Nle⁴, D-Phe⁷, D-Trp⁹]- α -MSH₄₋₁₁;
- j. [Nle⁴, D-Phe⁷]- α -MSH₄₋₉;
- k. Ac-[Nle⁴, AA⁵, D-Phe⁷, AA¹⁰]-R₁ or Ac-[Nle⁴, AA⁵, D-Phe⁷, AA¹¹]-R₂;
wherein AA⁵ may be either a L- or D- amino acid having an omega amino
30 or carboxyl group in the side chain, e.g., α , γ -diaminopropionic acid, α , γ -

diaminobutyric acid, Orn, Lys, α,β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

wherein AA¹⁰ may be diaminopropionic acid, α,γ -diaminobutyric acid, Orn, Lys, α,β -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

wherein R₁ is the designation α -MSH₁₋₁₃NH₂, α -MSH₁₋₁₂NH₂, α -MSH₁₋₁₁NH₂, α -MSH₄₋₁₃NH₂, or α -MSH₄₋₁₀NH₂;

wherein AA¹¹ may be L- or D- amino acid having an omega-amino or carboxyl group in the side chain, e.g., α,β -diaminopropionic acid; α,γ -diaminobutyric acid, Orn, Lys, α -aminoadipic acid, α -aminopimelic acid, or higher homologs, Glu or Asp;

wherein R₂ is the designation α -MSH₁₋₁₃NH₂, α -MSH₁₋₁₂NH₂, α -MSH₁₋₁₁NH₂, α -MSH₄₋₁₃NH₂, or α -MSH₄₋₁₀NH₂; and,

wherein Xxx may be from 1 to 5 α -amino acid residues each of which may be of L- or D- configuration, or a linear or branched chain spacer;

l.

m.

139

n.

wherein R^1 is a substituted or unsubstituted aromatic radical;

5 R^2 is hydrogen or a methyl group;

R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

R^4 is glutamic acid, alanine, -amino butyric acid, valine, leucine or isoleucine;

R^5 is histidine, glutamic acid, alanine, valine, leucine or isoleucine;

10 R^6 and R^7 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

R^8 and R^9 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

X and Y are sulfur, methylene, SO or SO_2 ;

15 Z is $-NH_2$,

and,

n is an integer greater than or equal to 2;

20

o.

wherein R¹ is phenyl, indole, p-hydroxyphenyl, p-aminophenyl, imidazole, 1-naphthyl, adamantyl or alkylphenyl, 2-naphthyl;

5 R² is hydrogen or a methyl group;

R³ is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂;

10

and,

n is an integer greater than or equal to 2; and wherein the cyclized portion of the compound is conformationally restricted in a manner which is compatible with the reactivity of the compound with receptors of the central nervous system.

15 33. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound is a peptide comprising an amino acid sequence represented by SEQ ID NO:1.

34. The invention of any one of Claims 1-9, 13, 15, 21 or 22, wherein said POMC compound has the following identifying characteristics: (1) an ability to bind to a POMC receptor that is expressed in peripheral tissues; and, (2) a biological activity selected from the group consisting of stimulation of lipolysis and inhibition of the uptake of fatty acids by adipocytes.

20 35. The invention of Claim 34, wherein said POMC receptor is selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R).

25

36. The invention of Claim 34, wherein said POMC receptor is a melanocortin 2-receptor (MC2-R).

37. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound binds to a melanocortin receptor selected from the group consisting of MC2-R and melanocortin 5-receptor (MC5-R), with a higher affinity than to melanocortin-4 receptors (MC4-R).

38. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound binds to a melanocortin receptor selected from the group consisting of MC2-R and melanocortin 5-receptor (MC5-R), and does not bind to any other melanocortin receptor under physiological conditions.

39. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound binds to MC2-R, and does not bind to any other melanocortin receptor under physiological conditions.

40. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound does not bind to MC4-R under physiological conditions.

41. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound preferentially activates melanocortin-2 receptors (MC2-R) as compared to melanocortin-4 receptors (MC4-R).

42. The invention of any one of Claims 1-10, 13, 15, 21 or 22, wherein said POMC compound does not activate MC4-R under physiological conditions.

43. The invention of any one of Claims 1-10, wherein said therapeutic composition is administered transdermally.

44. The invention of any one of Claims 1-10, wherein said therapeutic composition is administered topically.

45. The invention of any one of Claims 1-10, wherein said therapeutic composition is administered parenterally.

46. The invention of any one of Claims 1-10, wherein said therapeutic composition is not administered directly to the central nervous system of said animal.

47. The invention of any one of Claims 1-10, wherein said therapeutic composition is administered in a controlled release formulation.

48. The invention of any one of Claims 1-10, whereby administration of said compound is insufficient to cause a statistically significant change in the appetite of said animal as compared to before administration of said compound.

5 49. The invention of any one of Claims 1-10, 21 or 22, wherein said POMC compound is in a dose of from about 0.1 μ g to about 10 mg per kg body weight of said animal.

50. The invention of any one of Claims 1-10, 21 or 22, wherein said POMC compound is in a dose of from about 1 μ g to about 10 mg per kg body weight of said animal.

10 51. The invention of any one of Claims 1-10, 21 or 22, wherein said POMC compound is in a dose of from about 40 μ g to about 1 mg per kg body weight of said animal.

52. The invention of any one of Claims 1-10, wherein said POMC compound is from about 0.1% to about 90% of said therapeutic composition by weight.

15 53. The invention of any one of Claims 1-10, wherein said POMC compound is from about 0.1% to about 1% of said therapeutic composition by weight.

54. The invention of any one of Claims 1-9 or 11, wherein said method is effective to measurably decrease body weight in said animal.

20 55. The invention of Claim 54, wherein said decrease in body weight in said animal can be measured within at least about one week of said step of administering said compound.

56. The invention of Claim 54, wherein said animal has serum leptin levels between about 0 ng/ml and 50 ng/ml prior to said step of administration:

25 57. The invention of Claim 54, wherein said animal has serum MSH levels between about 0 ng/ml and 10 ng/ml prior to said step of administration.

58. The invention of Claim 54, wherein said animal has a ratio of serum MSH levels to serum leptin levels of greater than about 1:100 prior to said step of administration.

30 59. The invention of Claim 54, wherein said animal is a human having a body mass index (BMI) of greater than 27 kilograms per square meter.

60. The invention of Claim 54, wherein said composition further comprises another body weight regulating agent.

61. The invention of Claim 60, wherein said body weight regulating agent is leptin.

5 62. The invention of Claim 60, wherein said composition comprises a ratio of said POMC compound to leptin of about 1:100.

63. The invention of Claim 60, wherein said composition comprises said leptin in a dose of from about 0.1 μ g to about 100 mg per kg body weight of said animal.

10 64. The invention of any one of Claims 1, 3, 5, 7, 9 or 10, wherein said therapeutic composition is administered in an amount effective to measurably increase body weight in said animal or to decrease body weight loss in said animal.

65. The invention of Claim 64, wherein said compound is a proopiomelanocortin (POMC) antagonist compound.

15 66. The invention of Claim 65, wherein said compound has the following identifying characteristics: (1) an ability to bind to a POMC receptor that is expressed in peripheral tissues; and, (2) a biological activity selected from the group consisting of inhibition of lipolysis and stimulation of the uptake of fatty acids by adipocytes.

20 67. The invention of Claim 65, wherein said POMC receptor is selected from the group consisting of melanocortin 2-receptor (MC2-R) and melanocortin 5-receptor (MC5-R).

68. The invention of Claim 65, wherein said POMC receptor is a melanocortin 2-receptor (MC2-R).

25 69. The invention of Claim 65, wherein said antagonist compound is selected from the group consisting of a melanocortin antagonist compound and a lipocortin antagonist compound.

70. The invention of Claim 65, wherein said antagonist compound is a melanocortin antagonist compound.

30 71. The invention of Claim 65, wherein said antagonist compound is selected from the group consisting of a fragment of MSH having MSH antagonist action, a homologue of MSH having MSH antagonist action, a peptide mimetic of MSH having

MSH antagonist action, a non-peptide mimetic of MSH having MSH antagonist action, and a fusion protein comprising any of said MSH antagonist compounds.

72. The invention of Claim 65, wherein said antagonist compound is selected from the group consisting of α -MSH antagonist, β -MSH antagonist and γ -MSH antagonist.

73. The invention of Claim 65, wherein said antagonist compound is a peptide mimetic of MSH.

74. The invention of Claim 65, wherein said antagonist compound is an MSH analog selected from the group consisting of:

a.

b.

145

c.

wherein R^1 is a substituted or unsubstituted aromatic radical;

5 R^2 is hydrogen or a methyl group;

R^3 is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

R^4 is glutamic acid, alanine, -amino butyric acid, valine, leucine or isoleucine;

R^5 is histidine, glutamic acid, alanine, valine, leucine or isoleucine;

10 R^6 and R^7 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

R^8 and R^9 , which may be the same or different, are hydrogen, methyl or lower alkyl having one to five carbon atoms;

X and Y are sulfur, methylene, SO or SO_2 ;

15 Z is $-\text{NH}_2$,

and,

n is an integer greater than or equal to 2; and,

20

d.

wherein R¹ is phenyl, indole, p-hydroxyphenyl, p-aminophenyl, imidazole, 1-naphthyl, adamantyl or alkylphenyl, 2-naphthyl;

5 R² is hydrogen or a methyl group;

R³ is a carboxylate, carboxamide, hydroxymethyl, or aldehyde group;

X and Y are sulfur, methylene, SO or SO₂;

Z is -NH₂,

10

and,

n is an integer greater than or equal to 2; and wherein the cyclized portion of the compound is conformationally restricted in a manner which is compatible with the reactivity of the compound with receptors of the central nervous system.

15

75. The invention of Claim 65, wherein said POMC compound is combined with another body weight regulating agent.

76. The method of Claim 76, wherein said body weight regulating agent is selected from the group consisting of an anabolic steroid, a growth hormone, erythropoietin, a cytokine, and an anti-cytokine agent.

20

77. The invention of any one of Claims 1-11, wherein said animal is a human.

78. The invention of any one of Claims 1-10, wherein said composition further comprises an antagonist of MC4-R.

79. The invention of any one of Claims 1-10, wherein said composition further comprises an agent that inhibits binding of said POMC compound to an MC4-R.

80. The invention of any one of Claims 1-10, wherein said composition further comprises an agent which inhibits said POMC compound from entering the central nervous system of said animal.

5 81. The method of Claim 11, wherein said melanocortin receptor is melanocortin 2-receptor.

82. The method of Claim 11, wherein said step of modulating comprises administering to the periphery of said animal a compound which regulates said melanocortin receptor.

10 83. The method of Claim 11, wherein said compound is selected from the group consisting of a POMC compound, an antibody that selectively binds to said melanocortin receptor, and a soluble melanocortin receptor.

84. The method of Claim 11, wherein said step of modulating comprises administering an effective amount of a compound that increases expression of the melanocortin 2-receptor and induces weight loss.

15 85. The method of Claim 11, wherein said step of modulating comprises administering an effective amount of a compound that decreases expression of the melanocortin 2-receptor and induces weight gain.

86. The therapeutic composition of Claim 21, wherein said second body weight regulating agent is leptin.

20 87. The therapeutic composition of Claim 86, wherein said composition comprises a ratio of said POMC compound to leptin of 1:100.

88. The therapeutic composition of Claim 86, wherein said composition comprises a ratio of said POMC compound to leptin of 1:25.

25 89. The therapeutic composition of Claim 86, wherein said composition comprises a ratio of said POMC compound to leptin of 1:10.

90. The therapeutic composition of Claim 86, wherein said composition comprises said leptin in a dose of from about 0.1 μ g to about 100 mg per kg body weight of said animal.

30 91. The therapeutic composition of Claim 86, wherein said composition comprises said leptin in a dose of from about 0.1 μ g to about 10 mg per kg body weight of said animal.

92. The therapeutic composition of Claim 86, wherein said composition comprises said leptin in a dose of from about 1 μ g to about 10 mg per kg body weight of said animal.

5 93. The therapeutic composition of Claim 21, wherein said second body weight regulating agent is selected from the group consisting of an anabolic steroid, a growth hormone, erythropoietin, a cytokine, and an anti-cytokine agent.

94. The therapeutic composition of Claim 21, further comprising a pharmaceutically acceptable excipient.

10 95. The therapeutic composition of Claim 94, wherein said pharmaceutically acceptable excipient prolongs the presence of said therapeutic composition in the bloodstream of a animal.

96. The invention of any one of Claims 12-18, wherein said peripheral melanocortin receptor is MC2-R.

15 97. The invention of any one of Claims 14 or 15, wherein said test animal is a genetically modified non-human animal comprising a genetic modification within two alleles of its *Pomc* locus, wherein said genetic modification results in an absence of proopiomelanocortin (POMC) peptide action in said animal.

20 98. The genetically modified non-human animal of Claim 23, wherein said non-human animal comprises a genetic modification within two alleles of said *Pomc* locus, wherein said genetic modification results in an absence of POMC peptide action in said animal.

25 99. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a modification in a nucleic acid sequence comprising exon 3 of said *Pomc* locus, wherein said modification results in a reduction in proopiomelanocortin (POMC) peptide action in said animal.

100. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a modification within a region of said *Pomc* locus other than exon 3, wherein said modification results in a reduction in proopiomelanocortin (POMC) peptide action in said animal.

101. The genetically modified non-human animal of Claim 100, wherein said region of said *Pomc* locus other than exon 3 is selected from the group consisting of exon 1, exon 2 and a regulatory region of said *Pomc* locus.

5 102. The genetically modified non-human animal of Claim 23, wherein said genetic modification is selected from the group consisting of a deletion, an insertion, a substitution and an inversion of nucleotides in said *Pomc* locus.

10 103. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of a nucleic acid sequence within said at least one allele of said *Pomc* locus, wherein said deletion results in a reduction of expression of POMC peptides by said animal.

104. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of a nucleic acid sequence within two alleles of said *Pomc* locus, wherein said deletion results in an absence of expression of POMC peptides by said animal.

15 105. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of a nucleic acid sequence comprising exon 3 of *Pomc*.

106. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of exon 3 of *Pomc*.

20 107. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of a portion of exon 3 of *Pomc* sufficient to prevent expression of POMC peptides by said at least one allele in said genome.

108. The genetically modified non-human animal of Claim 23, wherein said genetic modification is a deletion of a portion of exon 3 of *Pomc* sufficient to prevent expression of POMC peptides by two alleles in said genome.

25 109. The genetically modified non-human animal of Claim 23, wherein said animal is a mouse, and wherein said genetic modification is a deletion from said genome of a nucleic acid sequence comprising SEQ ID NO:7.

30 110. The genetically modified non-human animal of Claim 23, wherein said animal is a mouse, and wherein said genetic modification is a deletion from said genome of exon 3 of *Pomc* (SEQ ID NO:7).

111. The genetically modified non-human animal of Claim 23, wherein said animal is characterized by a phenotype selected from the group consisting of obesity, a defect in adrenal development, and altered pigmentation.

5 112. The genetically modified non-human animal of Claim 23, wherein said animal has measurably increased serum leptin levels as compared to a wild-type sibling of said animal.

113. The genetically modified non-human animal of Claim 23, wherein said animal has an increased food uptake as compared to a wild-type sibling of said animal.

10 114. The genetically modified non-human animal of Claim 23, wherein said animal has measurably reduced serum levels of a hormone selected from the group consisting of corticosterone, aldosterone and epinephrine as compared to a wild-type sibling of said animal.

115. The genetically modified non-human animal of Claim 23, wherein said animal is a mouse.

15 116. The method of Claim 20, wherein said step of comparing is performed by an assay selected from the group consisting of morphological examination of said cells, tissues or body fluids; histological examination of said cells, tissues or body fluids; evaluation of POMC peptide biological activity in said animal; evaluation of free fatty acid metabolism in said animal; evaluation of lipolysis and fatty acid sequestration in said animal; evaluation of weight gain or loss in said animal; evaluation of hormone levels in
20 said animal; and, evaluation of blood biochemistry in said animal.

117. The method of Claim 25, further comprising obtaining progeny having said modification stably incorporated into their genome, wherein said modification results in an absence of expression of POMC peptides by said animal.

25 118. The method of Claim 5, wherein said affective and mood disorder is selected from the group consisting of depression and dysthymia.

119. The method of Claim 118, wherein said depression is atypical depression.

30 120. The method of Claim 6, wherein said obesity-associated disorder is selected from the group consisting of non-insulin dependent diabetes mellitus, cardiovascular disease, cancer, hypertension, osteoarthritis, stroke, respiratory problems, and gall bladder disease.

121. The method of Claim 7, wherein said reproductive disorder is selected from the group consisting of amenorrhea, an inability or reduced ability to ovulate, an inability to conceive, an inability or reduced ability to maintain a pregnancy, an inability or reduced ability to lactate, an inability or reduced ability to deliver a full-term offspring, and an inability or reduced ability to impregnate a female.

122. The method of Claim 8, wherein said pharmaceutical compound is selected from the group consisting of valproic acid, lithium, tricyclic antidepressants, and selective serotonin reuptake inhibitors (SSRI).

123. The method of Claim 10, wherein said eating disorder is selected from the group consisting of anorexia and bulimia.

124. The invention of any one of Claims 12-15, wherein said step of detecting is selected from the group consisting of measurement of melanocortin receptor transcription, measurement of melanocortin receptor translation, measurement of phosphorylation of melanocortin receptor, measurement of melanocortin receptor ligand binding activity, measurement of G protein activation, and measurement of melanocortin receptor translocation within a cell.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US99/29337

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : A01N 61/00, 43/04, 37/18; C07K 14/00; C12N 15/85

US CL : 514/1, 2, 44; 530/350; 800/3, 8, 9, 13, 21

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 514/1, 2, 44; 530/350; 800/3, 8, 9, 13, 21

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

WEST, STN, MEDLINE, CAPLUS, BIOSIS, SCISEARCH, PHAR, PHIC, PHIN

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X - Y	RICHTER et al. Physiologic Concentrations of Beta Lipotropin Stimulate Lipolysis in Rabbit Adipocytes. Metab. Clin. Exp., June 1985, Vol. 34, No. 6, pages 539-543, entire document.	2 ----- 1, 3-10, 15, 21, 22, 26-80, 86-95, 118-123
Y	KRUDE et al. Severe Early-Onset Obesity, Adrenal Insufficiency and Red Hair Pigmentation Caused by POMC Mutations in Humans. Nat. Gent. 19 June 1998, Vol. 19, No. 2, pages 155-157, entire document.	1-10, 15, 21, 22, 26-80, 86-95, 118-123
Y,P	WILSON et al. The Role of Agouti-Related Protein in Regulating Body Weight. Molecular Medicine Today. June 1999, Vol. 5, No. 6, pages 250-256, entire document.	1-18, 21, 22, 26- 97, 118-123

☒ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
B earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A* document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means	
P document published prior to the international filing date but later than the priority date claimed

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US99/29337

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
